REPORT OF THE COMMITTEE ON PUBLIC HEALTH NURSING

There has been only one meeting of this Committee since the last meeting of the House of Delegates and no business has been transacted. This meeting was at the St. Paul Hotel at the time of the Secretaries Conference. Dr. George Earl, Dr. T. E. Flinn and Dr. C. B. Wright were present.

The chairman has had numerous interviews with Miss Olivia Peterson in regard to an amendment to the Public Health Nursing Law providing that all nurses doing public health nursing work should be certified by a committee, the personnel of which was never quite settled upon. There were objections to this amendment on the part of sanatorium men and it was decided, therefore, on the part of Miss Peterson and her committee, not to present this amendment at this session of the Legislature.

There was no other business coming before the committee.

Respectfully submitted,
C. E. Caine,
George Earl,
T. E. Flinn,
C. B. Wright, *Chairman.*

Dr. Manley: The Reference Committee moves the adoption of this report.

Dr. Wright: The only thing I have to say is that I have spent quite a bit of time working with the University public health nursing school and I think we have accomplished a good deal. In other words, I think it is a good thing to have this committee. They tried to introduce a bill which would require all nurses loing public health work to take a course at the Uni-ersity before they could engage in such work. The dea, I think, is all right, but there was quite an ob-ection from some of the sanatorium men, some of hom train their own nurses, and we were able to kill he bill. The committee is doing quite a good work and think it should be continued.

Upon motion regularly made and seconded the report as adopted.

President Sogge: The report of the Committee on ontract Practice.

HE COMMITTEEE ON CONTRACT PRACTICE

The Committee on Contract Practice, consisting of ine members appointed December 9, 1930, has not ad any meeting during the year. The chairman re-uested the members, in a form letter, to suggest sub-ects which might be discussed or acted upon by this ommittee, and also requested an expression as to hether members wished to have a meeting. The gen-ral feeling was that a meeting was not necessary as here was nothing of importance to bring up for dis-ussion.

The Committee's report of 1929 was to the effect hat the situation as to contract practice was satis-actory to all concerned, and it was the sense of that ommittee that it should confine its activities to con-ideration of complaints on contract practice, as rought to its attention during the year. There have een no such complaints submitted for the attention of his committee.

Inasmuch as the tendency of the times seems toward roup practice in its various modifications, this com-ittee has not felt it wise to attempt any new line f investigation. Discussions of this subject in the terature is free and voluminous in publications deal-g with the economic side of medical practice. The tuation seems to be in a state of flux.

This committee, therefore, finds nothing definite upon hich to make recommendations for action by the tate Association.

Very truly yours,
Arthur N. Collins, *Chairman.*

Dr. Manley: The Committee on Contract Practice as not had a meeting during the past year. The Ref-rence Committee believes that there is a very large eld and a lot to be done in this line. We recommend hat the title of this Committee be changed to that of ndustrial Practice and that the committee be appointed the Council instead of the President, and that a esolution, by the Minneapolis Surgical Society which ill be considered in a few minutes, be handled by his new committee.

Upon motion regularly made and seconded, the re-ort was adopted.

President Sogge: The Committee on Military Af-airs.

Dr. Ralph T. Knight (Minneapolis): During the resent spring the county medical societies have been sked to appoint Military Affairs Committees, and a umber have already been appointed. This will give the state committee an opportunity to assist the local committees in—First—Arousing among eligible physicians interest in obtaining commission in the Medical Reserve. Second—Spreading information and enthusiasm among commissioned physicians so that they will retain their commissions and will advance in grade. Third—Keeping the profession as a whole informed as to what medical men are doing in military preparedness.

This committee will have from time to time some short bits of information which we would like to have inserted in Minnesota Medicine. It has been suggested by one of the members of the committee that there be a monthly department of a part of a column for Medico-Military facts, history, news and policies.

Dr. Manley: I move the adoption of the report of the Committee on Military Affairs.

The motion was regularly seconded and carried.

President Sogge: The report of the Committee on State Health Relations.

REPORT OF COMMITTEE ON STATE HEALTH RELATIONS

The Committee on State Health Relations has no definite recommendations to make to the House of Delegates at this time. Matters coming up through the year have been taken up with Council as they arose. We are studying the problem of local public health administration, with special reference to the "full time county health units" which have been advocated repeatedly. The medical profession has taken no stand, and no recommendation will be made by your committee until it has studied the matter further and obtained the views of the physicians in the various parts of the state.

Theodore H. Sweetser, *Chairman.*

Dr. Manley: I move the adoption of the report of this committee.

Dr. E. S. Boleyn (Stillwater): This committee met only twice during the past year and considered several things, but there wasn't anything in particular done.

Upon motion regularly made and seconded, the report was adopted.

President Sogge: We will now take up the resolution submitted by the Minneapolis Surgical Society.

RESOLUTION

Whereas, in the recent controversy over the reappointment of a member of the Industrial Commission statements were made that some members of this association were unfair to the employee by attempting surgical procedures for which they were not competent and were unfair to the insurance companies in their fees; and,

Whereas, there should be no antagonism but a feeling of kindly coöperation between the various agencies responsible for the care of injured employees.

Be it resolved that the State Medical Association appoint a committee whose purpose it will be to cooperate with the Industrial Commission in ascertaining the facts in cases where unfairness or incompetence is charged to members of this association, and to act as a group for the arbitration of all controversies.

James M. Hayes, *Chairman.*

Dr. Manley: The Reference Committee approves of this resolution and moves its adoption, and recommends that the committee suggested be given charge of these controversies relative to insurance companies. We thought that instead of the name Committee on Contract Practice, it should be changed to the Committee on Industrial Practice. A lot of men objected to the old name, and it really is a narrow definition, and the whole thing comes under industrial work, and if that committee is appointed, if our recommendation is accepted, we thought that things of this sort coming up would be handled by that committee.

Dr. J. M. Hayes (Minneapolis): The only object of this was to do away with some of the enmity of the insurance companies. Some of the things brought out in the Duxbury case were where doctors had rendered unfair fees and such things as that. We thought this might at least give the insurance companies the idea that the State Medical Association did not approve of that but rather wished to coöperate with the insurance companies in the matter of caring for the employees rather than being antagonistic to them. We thought especially that this committee already was composed entirely of so-called industrial surgeons, and we believed that if the committee could be composed of mixed surgeons rather than entirely industrial surgeons, better results might be accomplished.

Dr. Adams: In what manner does the committee act as an arbitration board?

Dr. Manley: The insurance company claims you are charging too much for your work. The committee takes it up and adjusts it.

Dr. Boyer: The purpose of that committee is to iron out certain difficulties; in other words, this committee gives us a chance to secure fair fees for the man who does work for the Industrial Commission, and gives us a chance to clean house ourselves instead of having the Industrial Commission do it. To present a glaring situation: Some man got a piece of iron in his side. The doctor was unable to extract it, but continued seeing the man every day or so until he had run up a bill of some $500.00, which the insurance company was obliged to pay. When his services were terminated the man was taken to a competent physician who extracted the piece of iron and in a few days the man was well. Such a matter as that would come under the cognizance of this committee.

President Sogge: You understand the Committee on Contract Practice is abolished by this motion and a new committee on Industrial Practice is to be appointed by the Council.

Upon motion regularly made, seconded and carried the resolution was adopted.

President Sogge: Now we have the report of the Special Committee to Study the Policies of the State Association.

Dr. O. E. Locken (Crookston): It was impossible to have this report written so you men could have it beforehand. We just presented it to the Council today. I might say this report has been discussed by the officers for three hours this morning and for three and a half hours this afternoon by the Council. I wish to ask for the privilege of reading the entire report first and then re-reading the summary and having the House of Delegates act upon the parts of the report.

REPORT OF SPECIAL COMMITTEE ON POLICIES

At the 1930 meeting of the House of Delegates of the State Medical Association in Duluth, the following resolution was passed:

"That a committee of five be appointed by the President to make a careful study of the policies of the State Medical Association, particularly along the lines of the consideration of the problems and development of the County Societies, of re-districting of the Association, accumulation of Reserve Fund, the organization of permanent committees, and changes in the personnel, on the duties of the executive officers, and to make such recommendations as they deem advisable for the best interests of the association and the component societies."

An amendment requested that this report be submitted to the Council for their opinion.

Dr. S. H. Boyer, President, appointed the following committee: O. E. Locken, Chairman, Frank Burch, W. A. Fansler, J. R. Manley, Waltman Walters.

This committee has made a study of the policies of the State Medical Association during the period of expansion since 1925. The committee has attempted to evaluate the activities of the society and to make certain recommendations which, it believes, will promote further service to the Association, the Profession, and the Public.

QUESTIONNAIRE

To assist the committee in determining the sentiment of the component societies on certain questions of policy, a Questionnaire was sent to the Secretaries of all of the County societies. Replies were received from 25 of the 36 societies. The 11 societies not returning answers have a total membership of 223 members or approximately only 10 per cent of the membership of the State Association.

Having the majority opinion of the majority of the societies with 90 per cent of the total membership, we felt that we had at least a general basis to judge the sentiments of the members of the Medical profession of Minnesota. We find that in general there is a definite satisfaction with the present system of organization, its policies and its accomplishments. There are some criticisms and some suggestions for improvement. These will be considered in the report which we, as a committee, have been asked to present.

REPORT

I. County Societies

The State Medical Association is made up of thirty-six component societies and has a total membership of

2,100 in 1930. Eliminating the four large societies of Hennepin, Ramsey, St. Louis and Olmsted, there are fifteen societies consisting of only one County. These have an average membership of 15. They are listed as follows: Blue Earth, 31; Dodge, 6; Freeborn, 17; Goodhue, 13; McLeod, 12; Meeker, 8; Mower, 22; Rice, 32; Steele, 9; Wabasha, 12; Waseca, 9; Washington, 13; Watonwan, 7; Winona, 24; Wright 14. The remaining societies consisting of more than one county are seventeen in number and have an average membership of 30.

It is the opinion of this committee that a Medical Society consisting of six or eight members must find it very difficult to maintain a constant high standard of scientific programs. We believe that it is a good policy for the average society to invite one or more guest speakers for some of its programs, but we candidly question if it is not an imposition to invite a guest speaker to travel a long distance to address a dozen men. We strongly recommend that an attempt be made by the smaller individual county societies to combine with one or more adjoining societies with the view of bringing their membership up to the average of 30 which the combined county societies have.

The individual county societies are in the Southern part of the State where the counties are small. With the automobile and the excellent highways there is no hardship to travel 25 to 50 miles to a meeting in the afternoon or evening. This step of combining societies along the lines suggested should be worked out by the societies themselves. We urge that the councilors in the districts affected should take the leadership in this redistricting of their societies.

II. Southern and Northern Minnesota Medical Societies

With greater emphasis placed on the local society, with the widening activities of the State Association, with the development of local hospital staff meetings, the average physician is beginning to feel that the demand on him to attend medical meetings is becoming too heavy. As a result there has come from different sources the suggestion that both the Southern and Northern Medical Societies be eliminated. Seven of the 25 societies who replied to the questionnaire expressed the desire that these two societies be eliminated. It is apparent that the majority feel that they be continued. It is our opinion and we so advise that the Northern Medical Association modify its plan to a one day session similar to that of the Southern Association. County Medical Societies could reduce the number of their meetings by one. The Southern or Northern Minnesota Society meetings could then be considered as one of the meetings in the series of each county society. This will overcome the objection of an additional meeting and will not detract from the State Association.

III. Administrative Organization of the State Association

The present plan of administration of the State Association is patterned after the earlier forms of representative democratic government. There seems to be no disposition to change to a direct election of officers such as we have now in civil life. The delegates selected by the component societies choose the council and the executive officers. Men are elected to office largely on their record of service to the Association. They have served an apprenticeship in committee work, in the House of Delegates, or in the Council until they are thoroughly familiar with the Society's problems.

The average doctor living an individualistic life has little opportunity to develop administrative ability. The increasing complexity of demands on the medical organization requires that it select its officers not only from men with scientific attainments, but from men who have served along the line of society activities until they are prepared for the higher positions. This idea is presented because from time to time criticism is heard presenting the feeling of dissatisfaction that the same old group is running the affairs of the organization year after year to the exclusion of other equally able men.

As rapidly as men show an interest in society problems and a willingness to give of their time, energy and money to serve the medical association, the State Association, in our belief, has always been and is ready to invite them to make those sacrifices. For these reasons the committee believes that the present policies are effective, satisfactory and essential.

IV. The Enlarged Program of Activities, Scientific, Educational and Legislative

1. Everyone seems to be satisfied with the constant improvement in the standard of scientific programs given at the Annual Meeting of the Association. This committee has no suggestions to make in reference to the scientific features of our State programs. However, the policy of permitting local committees of the host city to control arrangements other than the housing and entertainment is fundamentally wrong and is the cause of irritation and confusion. Space and arrangements for commercial and scientific exhibits should all be handled through the State central office. The income from exhibit space should go to the State Association. Expenses by the host city should correspondingly be assumed by the State Association from the revenues obtained. All details of program, selection of presiding officers at sectional meetings, speakers at banquets and every other detail of the arrangements for the meeting should be in the hands of the state rather than a local committee. We suggest that action be taken to establish this as a policy for the future.

2. The Public Health, State Medicine Relations and Economic Educational programs have been developed primarily for the purpose of creating public opinion favorable to scientific medicine as well as educating the public to the needs and benefits of higher standards of individual and community health. The results of such a program are of necessity intangible for it will always be impossible to strike a balance sheet on the benefits of a particular educational policy.

A variety of activities has been fostered to create a greater interest in Public Health education by the active committees in charge. Next to the Legislative Committee these various committees together have spent the largest sum of money in the budget of the Association. The use of Public Health Journals, Hygeia, Everybody's Health, Radio Talks, medical speakers for various groups such as Parent-Teachers and Educational Associations, weekly newspaper health stories mailed to rural newspapers and group meetings with the physicians themselves to encourage local medical leadership, have occupied most of the energies of these Committees.

These general efforts are of great indirect value. They represent a pioneer work of focusing the attention of the profession and the public on the importance of a properly conducted public health program. In addition to these activities it is our opinion that the State Association should particularly emphasize and center its efforts of public health education in the future on the following objectives:

a. Medical leadership should be encouraged in the County Public Health Associations which are the units of the Minnesota Public Health Association. To insure that medical leadership in County Health Associations will be provided for, we recommend that each component County Society appoint annually a special committee of its members whose responsibility it shall be to join and participate in the activities of each county Public Health Association and to keep the County Society informed of their Public Health Activities. A similar committee should be appointed for each county to make contact with the Red Cross organization. The importance of this is self evident unless we are willing to submit to the errors consequent to the inevitable lay leadership of local public health activities, free clinics and cultist influence.

b. Constant contact with the Public Health Nurses organization should be continued to avoid the difficulties of a few years ago when Public Health nurses had less of an understanding of the viewpoints of the Medical Profession in regard to Public Health.

c. Coöperation should be developed with the special committee which was appointed by the Minnesota Editorial Association for the purpose of creating a better understanding of the viewpoints of the Medical profession in regard to the subject of advertising. There is no disposition on the part of physicians to change their long standing ethics on this subject. There should, however, be a disposition to foster a friendly feeling with the newspaper profession for the mutual benefit of the public, the publishers and the doctors. Control of quack advertising, the presentation of scientific facts to the public in place of the customary news stories of unsupported, unestablished scientific discoveries can only come when the doctor and the publisher have established a different relationship than exists today. Conferences for the purpose of creating a better understanding of this problem can do no harm and may bring new viewpoints of value. It is recommended that county societies be required to appoint a special committee to serve in each county for the purpose of making contact with the newspapers. Such a committee could also add to its field the troublesome problem of regulating medical speakers before lay audiences. Such regulation is for the purpose of avoiding irritation in the profession itself, reducing to a minimum undesirable professional publicity and to safeguard the public in the type of information given them.

d. University Relations. Most of the physicians practicing in Minnesota are graduates of our own University. Most of the future practitioners will be graduates of that institution. It is natural, therefore, that the State Medical Association has a hearty interest in the education and training of Medical students. There is definite evidence that whenever and wherever medical men convene and discuss the subject, that the University Medical School and Hospital have not even half-hearted support of the profession. Underlying this is the considerable difference of opinion on such questions as pay patients or free patients in dispensary and the University Hospital; a teaching staff comprised of scientists who have never engaged in the private practice of medicine; a students health service providing complete medical and surgical facilities to rich and poor alike, with an increasing emphasis on the treatment of disease rather than only its prevention, and increasing tendency to produce laboratory trained physicians at the expense of such additional factors in the practice of medicine that lead to the field of ethics, philosophy, psychology, economics, community contacts, and medical association problems, all of which occupy so much of the average physicians life and success.

We strongly recommend the continuation of a Public Policy Committee known as the University Relations Committee, to work regularly with a similar Committee from the Medical School and a Committee from the Medical Alumni Association. Such a committee might well aid or advise in formulating policies, regarding the recommendation and admission of patients to the University Hospital, discuss and formulate plans for extra-mural teaching, University Extension courses, and Public Health Clinics, in which the University teachers take part or coöperate with the local medical bodies, aid in securing University appropriations and funds for University research, for hospital development and for endowments. Such a committee should serve as a clearing house of sentiment and an aid to the President of the University and the Dean of the Medical School regarding problems of medical education, clinical teaching, and qualification standards.

It is our opinion that successful contact with these four groups: The Minnesota Public Health Association, The Public Health Nurses Association, the Minnesota Editorial Association and the University, will increase the value of the general medical educational program for the public through such agencies as lectures, radio talks, clinics, and news service. In making this suggestion we fully recognize the successful methods in which these general agencies have been carried out. To attack the problem of public health education from the basis now recommended we believe is fundamental and more productive of lasting results.

3. The activity of the State Association in medical legislation in the past six years has received greater emphasis than any other effort of the Society. The achievements have been so striking as to represent an entirely new era in the history of our Association. The most important acts were the passage of the Basic Science Law which prevents untrained cultists to practice the healing art in Minnesota; the revision of the Medical Practice Act requiring higher standards of training and practice; the reduction of the period in which malpractice suits could be started from six to two years; the Massage Bill placing the licensure in the hands of the State Board of Medical Examiners, thereby restricting the unlimited use of the title of Doctor by the masseurs; the securing of $25,000 appropriation for research work at the University; the continuation of the Venereal Disease laboratory of the State Board of Health; the prevention of fees for medical service being dictated by the Workmen's Compensation law. Other more indirect results of value were accomplished by the prevention of the passage of such bills as anti-vaccination, anti-vivisection, cultists practicing in tax supported hospitals, the licensing of naturopaths to treat the sick, and the permission of osteopaths to increase their rights to practice allopathic medicine.

A summary of such a varied program of medical legislation gives an understanding of the aggressive front which the medical profession has taken both in its own behalf and in the protection of the public.

Because this program has cost considerable money there has been a reaction on the part of some members of the Association against it. Others have objected to the work on the principle that the methods used to accomplish the results are objectionable.

From answers to the Questionnaire, twenty-three of the twenty-five societies replying were satisfied. One was tolerant and in one society from which individual reports were received from 26 per cent of the membership, 25 per cent of those answering were not satisfied. This group comprised 6 per cent of the total membership of the society.

In view of this nearly unanimous expression of satisfaction with the work of the legislative program of the State Association, this committee, in analyzing its results, merely wishes to confirm the general opinion that the legislative committee has accomplished a heroic work, that its members have sacrificed much of their time and energy, that we have the fullest confidence in the judgment of the men who have continued the six year fight for medical legislation. We find that the State Association has rewarded these men in the only manner at its command, by electing them to the honor of the highest positions in the state organization.

The following principles can be accepted as the policy of this Association: (1) That Association expenditures for legislative purposes be predetermined by special budget of the council and such a special fund be audited as in the past by the council. That such expenditures be kept within this budget. (2) That lobbying in the interest of legislation affecting medical practice and Public Health be maintained as far as possible on a basis of advancing information as to the views of the profession and the needs of the public.

We believe that the policy of not asking for any further legislation from the 1931 legislature should, as far as possible, be continued through another session.

The excellent relationship which now exists between the legislature and the medical profession could best be maintained by asking for no further favors other than the maintenance of the high standard of medical legislation now on the statutes of Minnesota.

V. Financial Reports and Dues

The committee has reviewed the audits of the State Association since 1925 and presents a comparative outline of the main divisions of income and expenditures covering each of the years from 1925 to 1930, a chart of which is hereby submitted.

Year	1930	1929	1928	1927	1926
Investment Fund	$23,737.37	$22,735.76	$21,000.00	$11,700.00	$ 9,000.00
Income	31,140.00	30,924.75	31,200.00	30,419.00	10,185.00
1. Dues	27,014.00	26,818.75	27,084.00	26,391.00	6,157.00
2. Subscriptions	4,126.00	4,106.00	4,116.00	4,028.00	4,028.00
Magazine	12,408.91	12,562.63	12,619.18	12,755.00	13,982.95
Miscellaneous and interest	537.57*	1,296.58	1,340.74	687.11	817.36
Total income	$39,960.48	$40,677.96	$41,043.92	$39,834.03	$20,957.31

*Less $1,001.61 interest on and added to Investment Fund.

EXPENDITURES

	1930	1929	1928	1927	1926
Administrative	$10,670.48	$10,674.67	$ 8,967.62	$ 9,086.73	$ 6,238.72
Committees:					
Education and Legislation	5,117.03	18,361.52	2,296.39	14,254.59	143.85
Public Health	5,899.06	4,274.90	3,737.71	2,033.77	3.00
Minnesota Medicine	14,023.37	12,090.12	11,833.07	12,679.94	13,057.86
Miscellaneous	262.37	....	....	....	....
Total	35,972.31	46,026.71	27,155.32	38,070.28	19,443.43
Deficit or Surplus	+3,988.17	—5,348.75	+13,888.70	+1,763.75	+1,513.88

1925
Special assessment for legislation
$6,971.09—1925
2,335.00—1926
$9,306.09

1925
$5,145.12 spent in 1925
4,160.97 spent in 1926

The following facts are observed:

Since the dues were raised in 1927, the annual income has doubled and has so remained approximately $40,000.00 from dues, magazine, and interest. The membership of the State Association remains the same, approximately 2,000 members.

The income of the magazine remains the same, approximately $12,000.00.

A review of expenditures shows that expenses for administration have advanced from approximately $6,000.00 in 1926 to $10,000.00 in 1930 but that there has been no increase in the past two years, indicating the arrival now of a fixed policy.

The expense of the legislative program has been variable in relation to the legislative years. The expenditures of approximately $14,000.00 and $18,000.00 respectively in 1927 and 1929 undoubtedly represent the peak of funds that will have to be expended for such purposes. With the fundamental laws on medical legislation now on the statutes, the State Association must concern itself chiefly with holding the ground that it has gained. A policy of defense can not require as great a cost as the heavy work of offense in the past few years.

The expenditure of funds for Public Health education, State Medicine and economic study and contacts from $3.00 in the year 1926 has been increasing at the rate of about $1,000.00 a year until it became approximately $6,000.00 in 1930. We have already in previous sections of this report presented recommendations for the immediate future policy of this activity. Following these suggestions further increases will probably not be necessary.

The expenditure for our magazine, MINNESOTA MEDICINE, has remained essentially the same until 1930 when it increased $2,000.00, to a total of approximately $14,000.00. We feel that our medical journal has been constantly improving and that these expenditures are acceptable to everyone.

The question of the present dues is entirely a matter of the general policy of the State Association directed towards the two flexible divisions of our activities, legislation and Public Health education. In replies to the Questionnaire on this subject only three of the 25 societies expressed the desire that the dues be reduced, most of them felt that they should be maintained but should not be increased. This committee feels that annual dues of $15.00 since 1927 have been essential and that the income derived has been properly spent to carry out the wishes of the majority of the State Association.

The future level at which dues shall be placed must depend wholly upon the activities which the society fosters. This can only be determined from year to year. It would be unwise to make any change until the results of the present policies can be further evaluated. Two years from now we will be in a better position to determine that question. Until then no further action should be taken.

The Investment Reserve fund now totaling $23,737.37 is the result of a gradual accumulation of savings over a great many years. The money is invested in high class bonds. Additions to this fund in the past years have come only from the earnings of interest from the fund itself. The advisability of continuing this policy has been questioned by some members. It has been created primarily because of a general policy of all business and fraternal organizations to protect themselves with some form of reserve fund. There has been no disposition on the part of the officers of the association to use any part of this accumulated fund for expenses of running the association. It has been suggested that it might be used for needy physicians, for scientific research, for the promotion of scholarship at the medical school or be kept only as an emergency fund for any unusual demand on the association which might arise.

It is our opinion that this fund should be allowed to increase and that additions to this fund should come as in the past from savings in the management of the State Association. We recommend that prizes be given for scholarship to medical students. Such an act would at once foster a contact between the undergraduates and the State Association, a relationship which is obviously advisable and of value to both. An annual stipend for a graduate fellowship in special investigative work would also indicate our interest as a profession in medical education. The interest earned on our reserve fund should carry such a policy.

VI. Minor Questions

Various other questions have been brought to the attention of the committee for consideration.

1. Shall the Medical Journal stress other subjects than scientific and Association reports? So much is being written on the economic side of medical practice in lay magazines that there is some demand that these subjects be discussed in our Journal. It is our opinion that any steps taken in that direction should be taken very slowly. Special articles and editorials on this subject from time to time should be welcome but it is not advisable at this time to create any special department in the magazine on economic questions. The subject of economics should be left to the Editorial Committee.

2. The Reference Committee in one of its reports to the House of Delegates recommended that the office of Secretary and Treasurer be combined to expedite the routine business of the Association. In view of the policy of having all accounts audited by certified public accountants, a separate Treasurer's report has been considered less essential. The expenditures of funds is now wholly at the discretion of the Council. If in the opinion of the Councilors the combining of the offices of Secretary and Treasurer will increase the efficiency of their routine business such a change should be made. Our committee feels that the House of Delegates should take no action except on the recommendation of the Council.

3. The Association has employed a group of attorneys, Oppenheimer, Dickson, Hodgson, Brown and Donnelly, for many years. In recent years Mr. Brist has done

much work for our Legislative Committee. He is also the Attorney of the Board of Medical Examiners and as such has carried on the successful prosecution of illegal practitioners of medicine. We believe his work will be more effective if he is not in the direct employ of the Medical Association as its regular attorney. Representing the State Board of Medical Examiners rather than the medical profession, places him in a stronger position before the Courts. We, therefore, recommend that the present relationship be continued and the present group of Attorneys be retained as in the past. Mr. Brist, however, could be employed as a special attorney by any committee authorized by the Council for any special purpose and for which a suitable retainer's fee should be paid.

SUMMARY OF RECOMMENDATIONS

1. That the small individual county societies should combine when feasible, with adjoining societies to bring their membership up to approximately the average of 30 now existent in the other combined county societies.

2. That the Northern Minnesota Medical Association limit its annual meeting to a one day program. That both Northern and Southern Societies meetings should be considered as one of the annual series of the County societies in their respective district.

3. That the present plan of administration of the State Association be continued.

4. That all arrangements for the Annual Meeting be handled by the State central office and by State committees with the exception of such matters of entertainment that the local host city is prepared to give. That income from commercial exhibits should go to the State Association and that it in turn should correspondingly assume expenses for the meeting.

5. That the Public Contact Program be continued as in the past and special emphasis directed toward: (1) Medical Leadership in County Public Health Associations. (2) Constant contact with the Public Health Nurses Association. (3) Coöperation with the Minnesota Editorial Association. (4) Coöperation with the University Medical School.

6. That in the policy toward medical legislation the Association appreciative of the present high standard of medical statutes as far as possible ask no further immediate favors from the legislature except to continue the principles now established; that expenditures for legislative activities be budgeted and audited by the Council.

7. That toward the problem of finance the Association restrict its expenditures in both legislative and educational activities to a level that can be met with its income.

8. That the policy of developing a reserve fund from savings in the management of the Association be continued. That when deemed feasible steps be taken to give prizes and scholarships, both undergraduate and graduate, to the students of the medical School to indicate the interest of the Association in medical educcation.

9. That the Medical Journal MINNESOTA MEDICINE continue its present policy of serving as an organ for scientific articles and association activities. The subject of Economics should be left to the Editorial Committee.

10. That the question of combining the offices of Secretary and Treasurer be decided on the recommendation of the Council.

11. That the present group of Attorneys of the Association be retained.

CONCLUSION

The committee which was appointed by Dr. Boyer to prepare this report consists of men who have had no direct relation with the organization of the activities of the State Association in the years of its expansion. We have approached each question of policy from as unbiased a viewpoint as possible, attempting to base our recommendations both by ascertaining the sentiment of the entire membership of the association, and by exercising freely our own judgment. We trust this report will serve as a basis of information of the essential policies and activities of the Minnesota Medical Association. In analyzing the work of the Association the committee has itself obtained an appreciation of the achievements of the Society. We hope the general membership will be equally stimulated by reading this summary of the efforts of the Association. The Minnesota Medical Association has been in the hands of high minded, capable men. We anticipate that it will continue to be so in the future.

As a special committee we wish to express our appreciation for the courtesies that have been extended us from the officers, the component societies and the entire membership in assisting us to obtain the information on which the report is based.

O. E. LOCKEN,
FRANK BURCH,
W. A. FANSLER,
J. R. MANLEY,

PRESIDENT SOGGE: I think the only way we can get at this is to have Dr. Locken read the summary, paragraph by paragraph, and take action on each paragraph.

DR. WRIGHT: I wonder if it would be possible for the members to talk this thing over and discuss this report at the meeting tomorrow.

SECRETARY MEYERDING: We hope the House of Delegates will convene tomorrow at 11:30 A. M. in Parlors O. P. and Q, where luncheon will be served. I don't know how much business will come up tomorrow; we have election of officers, but perhaps this could be taken on.

DR. ROBBINS: I move that we lay the report over until tomorrow.

DR. KLAVENESS: In order that you may know my opinion about the whole report, I would say it is the most interesting analysis of the functions of our State Association that I have ever listened to, and the Committee has certainly done itself proud by covering the field so completely. However, while I concur with the recommendation that the smaller counties should join and make up into larger societies, they have apparently forgotten the policy of the State Association to recommend a redistricting of its Association with reference to the Councilor districts. I speak particularly for Wright County, which is adjacent to Stearns and Benton Counties. It is manifestly out of the question to expect that Wright, Stearns and Benton counties will ever have a councilor given to them when they are in with Hennepin County which has 524 members. We would be glad to join with Stearns and Benton counties and leave Hennepin County by itself.

President Sogge: You have heard the motion that we take up this report tomorrow. All in favor signify by saying "Aye." I think we had better have a division on that.

The vote was 26 to 24 so the motion is carried.

The Council recommends that Dr. T. R. Moran, St. Luke's Hospital, St. Paul, Dr. F. C. Mann, Mayo Clinic, Rochester and Dr. W. C. McCarty, Mayo Clinic, Rochester, be elected to associate membership. What is your wish?

Upon motion regularly made and seconded the recommendation of the Council was accepted and Drs. Moran, Mann, and McCarty declared associate members of the Minnesota State Medical Association.

President Sogge: There has been suggested a new plan for membership certificates, with the name of the local society and the local secretary. Dr. Meyerding will explain it.

Secretary Meyerding: At the Secretaries' Conference the question of adding to your membership certificate the name of the local society and the local secretary was discussed. I have a few proofs here of a suggested certificate. It means that in your office when you put up your certificate the name of your local medical society and your secretary would appear on it. We sent out a questionnaire to the various societies in the state and 26 reported favorably. The Council discussed this this afternoon and it thought the best plan would be to have the name of the local Society and the secretary's signature stamped in our office so every member would receive his certificate promptly. The size of the certificate will be the same as it has been in the past. The Council recommends that the new plan be tried for a year and that the certificates be mailed directly from the state office.

Dr. Robbins: I move that the plan be adopted.

The motion was regularly seconded, put to a vote and carried.

Dr. C. L. Scofield (Benson): It seems our By-Laws provide that the House of Delegates shall meet at 2:00 P. M. on the first day of the meeting. That is not necessary, and I offer this amendment to Chapter 5, Section 1; that the words "At 2:00 P. M." be stricken out, and that this be considered at the meeting tomorrow.

Dr. Robbins: I have this resolution to offer: "Resolved that the House of Delegates of the Minnesota State Medical Association go on record urging the component societies to incorporate in their public health educational programs a study of the health conditions of the Indian population, and its relations to the general public." I move that the resolution be referred to the Reference Committee for a report tomorrow at the meeting of the House of Delegates.

Upon motion regularly made and seconded the report was adopted.

Dr. N. O. Pearce gave a talk on Medical Economics, illustrated by slides.

SECOND MEETING OF THE HOUSE OF DELEGATES

The second meeting of the House of Delegates of the Minnesota State Medical Association at the Nicollet Hotel, Minneapolis, was called to order at twelve, noon, May 5, 1931, by President Sogge.

President Sogge: Gentlemen, come to order please. We will have the roll call.

Secretary Meyerding called the roll.

President Sogge: All those who have not turned in their credentials, please do so.

A summary of the minutes of the previous meeting was read by Secretary Meyerding.

President Sogge: Next is the report from the Council.

Dr. Workman, Tracy, read the report of the Council.

SECOND MEETING OF THE COUNCIL

The second meeting of the Council was held Monday night after the meeting of the House of Delegates adjourned.

The following were present: H. M. Workman, W. W. Will, M. S. Henderson, W. A. Coventry, F. J. Savage, A. G. Schulze, O. J. Hagen, Wm. A. Piper, and E. A. Meyerding.

The question of redistricting the Councilor districts was discussed. Motion made by Dr. Coventry, seconded and carried that a Committee of two Councilors be appointed to look into this matter of redistricting the Councilor districts and the amalgamation of some of the component societies. Drs. Coventry and Henderson were appointed.

The meeting adjourned.

President Sogge: We will have the report from Dr. Watson, Chairman of the Committee to Coöperate with the Editorial Association.

Dr. J. A. Watson (Minneapolis): Most of you know something about this Committee, about its conception and so on. The Editors started to interest themselves in the question of whether or not there should be a broader attitude on the part of the medical profession toward advertising. They soon saw that it was a matter of evolution that it would have to be left to the medical profession. One thing led to another until they requested that a committee from the Minnesota State Medical Association be appointed to confer with a committee of their own association, the Minnesota Editorial Association, with a view of establishing closer relations between the two professions, so that something would grow out of it in the future.

While we were very skeptical in the first place as to whether it would ever amount to anything, it has come to the point where those of us who were appointed members of the committee think that good might grow out of it and may result in something valuable to the medical and editorial professions. These committees had a breakfast meeting this morning at which the following men were present:

Dr. J. A. Watson, Minneapolis
Dr. S. H. Boyer, Duluth
Dr. H. M. Workman, Tracy
Dr. O. O. Larsen, Detroit Lakes
Dr. E. A. Meyerding, St. Paul
Mr. Roy Dunlap, St. Paul
Mr. J. Jones, Minneapolis
Mr. H. E. Soule, Minneapolis
Mr. A. E. McGowan, Minneapolis
Mr. L. Benshoof, Detroit Lakes

Mr. Benshoof was the originator of this whole question. It started rather acrimoniously and has settled down into something quite harmonious.

After a good deal of discussion the following resolution was adopted:

"Be it RESOLVED, That this conference favor the formation of an Advisory Board of Public Relations between the Minnesota State Medical Association and the Minnesota Editorial Association, consisting of five representatives of each organization. It is the sense of the conference that the representatives of the two associations be selected so as to have representation of the state at large."

President Sogge: What do you want to do with this report?

Dr. E. Klaveness (St. Paul): I move it be accepted.

Dr. W. A. Coventry (Duluth): As a substitute motion I move the report be accepted and the recommendation of the report that a committee of five be appointed, be carried out by the Council.

The motion was regularly seconded, was put to a vote and carried.

President Sogge: University Relations, Dr. Boyer.

Dr. S. H. Boyer: The University Relations Committee, after several meetings, has arrived at this conclusion and submits this report:

REPORT OF UNIVERSITY RELATIONS COMMITTEE

Members of the Committee on University Relations have coöperated with the Medical Alumni Association during the past year in studying various problems confronting the medical school. It became apparent that many of the shortcomings of the medical school had their origin in a lack of executive ability and of practical leadership on the part of the Dean. There was also considerable criticism of the methods employed in teaching the practical side of medicine. The Medical Alumni Association had come to a similar conclusion, and your committee endorsed a resolution which they sent to the Chancellor of the University and the Board of Regents, in which a change in the deanship of the medical school was requested.

We regret that the Chancellor of the University has not deemed it advisable to take any steps to remedy the conditions suggested by the resolution, and that the situation has been allowed to remain as it was before.

L. Sogge
S. H. Boyer
W. F. Braasch
J. T. Christison
H. M. Workman
C. B. Wright

President Sogge: You have heard this resolution. What do you wish to do with it?

Dr. Coventry: I move the report be accepted and placed on file.

The motion was regularly seconded, was put to a vote and carried.

President Sogge: We have an unusual honor today in having the President of the American Medical Association with us. He is a man that we are proud of because of his ability, and we are proud of him because he is President of the greatest medical organization in the world. I would like to have him stand up and speak to us just a few minutes, Dr. E. Starr Judd.

The audience arose and applauded.

Dr. E. Starr Judd (Rochester): One of my principal jobs now seems to be to try to learn something about organized medicine. I knew nothing about it a year ago, but I know very much more about it now.

One thing I have found out is that the Minnesota profession is really organized, better than any other state. That is largely due to the efforts of Dr. Meyerding and the Councilors. As you know, the state society, public health activities and all medical activities are under the control of Dr. Meyerding and the Councilors. I think that this is being recognized throughout the country. Very many of the state organizations are following our example in that respect. (Applause).

President Sogge: We will hear a resolution from the Secretary.

Secretary Meyerding: Last night Dr. Robbins of Winona presented a resolution that was referred to the Reference Committee but the Chairman is not here. I think that if I read it again you can take action.

This resolution is simply in conformity with one of the trends of public opinion. As you know, there is a great deal of interest now taken in the Indian. This is just a suggestion on the part of the House of Delegates, as I understand it, for the local society to cooperate with the public in studying Indian health. It reads as follows:

"Resolved, That the House of Delegates of the Minnesota State Medical Association go on record urging the component societies to incorporate in their public health educational programs a study of the health conditions of the Indian population, and its relation to the general public."

President Sogge: What do you want to do with this resolution?

Dr. E. S. Boleyn (Stillwater): I move that it be accepted and filed.

The motion was regularly seconded, was put to a vote and carried.

President Sogge: Amendment to the By-laws read last night.

Secretary Meyerding: Dr. Scofield introduced an amendment to Chapter V, Section I.

The By-laws say that we shall meet at two p. m. on the first day of the meeting. That caused a little trouble this year. We are simply striking out the words "two p. m." so we can set the hour.

Dr. H. M. Workman (Tracy): I move that it be adopted.

The motion was regularly seconded, was put to a vote and carried.

President Sogge: We will now continue with the report of Dr. Locken.

Dr. O. E. Locken (Crookston): Mr. President, when this Committee was appointed, and as we have drawn up this report, it was our opinion that there was nothing mandatory about what we recommended as far as the future policy of the Council was concerned, in carrying out these recommendations. It was our understanding that we were merely asked to make a survey of the sentiment of the organization and report back to you these recommendations.

We discussed this report very carefully all afternoon yesterday, and there was a great deal of discussion, pro and con. It seemed to me the whole thing was taken on the wrong track, that if we adopted this report it was mandatory on the Council to carry out every one of these recommendations. It is our idea that it is simply a matter of aid to the Council as an indication of what a disinterested group of five men thought about the policies of the organization, from a survey they made in an attempt to get the opinion of the entire organization. We do not wish to be in the position that we want to argue or defend any of these recommendations but merely express them. If any members of the House of Delegates have opinions contrary, I think it is proper that they get up and discuss those questions, so their opinion may be of help to the Council. I think if we have that understanding we will probably avoid a great deal of argument over some of these things and save some time, and make it possible for us to get to the clinics this afternoon. If that idea is correct, we can approach this report from that standpoint. I will read the summary of recommendations again.

President Sogge: Read them paragraph by paragraph.

Dr. Locken: If there is no dispute about them, it is not necessary to discuss each point.

"1. That the small individual county societies should combine, when feasible, with adjoining societies, to bring their membership up to approximately the average of 30 now existent in the other combined county societies."

President Sogge: I understand the Council took this matter up last night, and I would like to hear from Dr. Coventry what the recommendation was.

Dr. Coventry: We have discussed that in the Council off and on for the last year or so. There are two problems: One, amalgamating some of the smaller societies, and the other, redistricting the state as far as the Councilors are concerned.

A motion was made last evening and carried that the Council appoint a committee to survey the question of drawing the weaker societies in with the stronger ones, and also surveying the state as to redistricting, rearrangement, so far as Councilors are concerned. As I say, that motion was carried and a committee has been appointed. It seems to me, Mr. President, that will take care of the matter to the satisfaction of everybody.

President Sogge: Do you want to take action on the report from the Council, approve it, or anything to that effect?

Dr. J. R. Manley (Duluth): I move it be approved.

The motion was regularly seconded, was put to a vote and carried.

Dr. Locken: "2. That the Northern Minnesota Medical Association limit its annual meeting to a one-day program. That both Northern and Southern Societies meetings should be considered as one of the annual series of the county societies in their respective districts."

Dr. B. S. Adams (Hibbing): I think the Committee is absolutely right that one day is sufficient. I agree that there is a superfluity of medical meetings. However, the sentiment expressed to me is that the north would like to get together once in a while, and they want to continue the Northern Minnesota Medical Association and I presume in the southern part of the state they want to continue the Southern Minnesota Medical Association.

There is one thing that comes to my mind in connection with the meeting at Hibbing, and the same will apply more to meetings of the Northern Minnesota Association than to meetings of the Southern Minnesota Association, and that is the distances that we have to travel. We could have the meetings start early in the morning at Hibbing and finish up that night, but we have no sleeper trains coming into Hibbing. Anybody coming by way of Duluth will not get to Hibbing until ten forty-five. If they drive, they have to come up the day before, unless they want to do some night driving.

I am wondering if it wouldn't be better to have our meetings start, say, at one o'clock noon and on until eleven or twelve o'clock the next day. That will give those, that want to, a chance to drive. It will mean only one night away from home. Then on Saturday afternoon, after the meeting is over, we can give them a trip through the ore pits in an observation car, or they can go home. That is just a suggestion. We can work it out either way it seems advisable. We would like to get your advice.

President Sogge: Is there any further suggestion or discussion? I suggest that the resolution be sent to officers of the Northern and Southern Minnesota Medical Associations, because we can't take action on it, as far as I can see.

Dr. Boyer: Of course, this recommendation is not mandatory. It is simply given out to the Northern and

Southern Minnesota Medical Societies and, of necessity, to the component societies of the state organization, because, in the last analysis, it must be through the action of all of these bodies, as they see fit to consummate or follow out this recommendation. So it resolves itself, after all, into more or less of a local action. There is nothing that we can do.

President Sogge: Would you recommend that this go to the officers of the associations?

Dr. Boleyn: I so move.

The motion was regularly seconded.

President Sogge: It has been moved and seconded that this resolution be sent to the officers of the Northern Minnesota and Southern Minnesota Associations. All those in favor say "aye"; contrary "no." It is carried.

Dr. Locken: "3. That the present plan of administration of the State Association be continued."

President Sogge: What do I hear on that?

Dr. Boleyn: I move that it be adopted.

The motion was regularly seconded, was put to a vote and carried.

Dr. Locken: "4. That all arrangements for the annual meeting be handled by the state central office and by state committees with the exception of such matters of entertainment that the local host city is prepared to give. That income from commercial exhibits should go to the State Association and that it in turn should correspondingly assume expenses for the meeting."

President Sogge: What will you do with this recommendation?

Dr. M. S. Nelson (Granite Falls): I move it be adopted.

The motion was regularly seconded.

Dr. F. H. Magney (Duluth): I think before this is settled you should know our attitude in Duluth. We have had two State Association meetings since the practice of selling space was adopted by the State Association. We spent the money collected, first of all, to put on a good meeting at Duluth. The net proceeds we put in the Library Fund, and not one cent has been used for any other purpose. We are trying, if possible, to build up a library in Duluth that will be available to those in the northern end of the state. We are rather distant from the medical center here and we need a library. That is the only purpose we will use the money for.

I think before this is definitely settled it should perhaps be given a little further consideration, perhaps by a committee.

Dr. Locken: I took the liberty last evening, after our meeting, to go around and talk to some of the exhibitors to get their frank viewpoints on this. This isn't any reflection on the people of Minneapolis who have been responsible for the program, but there was definite dissatisfaction on the part of the exhibitors in the way their space has been handled. They have gone so far as to appoint a special committee of three members to handle affairs for them in the future, in their own defense. It is an indication that the exhibitors themselves feel that under the present system they are not being given an equal and fair handling in the space they require. We discussed the angle from the standpoint of the Association. I just wanted to offer that information.

Dr. J. P. McDowell (St. Cloud): Dr. Magney of Duluth has a good idea, but I will warn you that if any of the smaller towns want to put on the meeting in their town, they had better figure differently. They aren't going to get any library, but they are going to go down into their pockets, because we put on the Association meeting at St. Cloud a few years ago and I have had definite orders not to let it come up again because it costs too much money. I don't think myself that it was an advantage to the Association to meet in a small town. Don't ask for it unless you know where you are going to get off at.

President Sogge: Is there any further discussion.

Secretary Meyerding: For three or four years the Secretary has brought up the question of the commercial exhibits being handled by the central office. An exhibit of that type is like any other. You have to build up a clientele and make the acquaintance with those people. As Dr. Locken brought out, there are certain things they don't want, and they are more or less dissatisfied.

In the past few years we have had fairly good success. This is an excellent exhibit. It has been well run, in spite of the criticism the men make. They are a little crowded but it is the best thing that could be done. Last year at Duluth there were empty booths. The same thing happened at St. Paul.

The expense of the meeting is gradually increasing. The State Association has assumed more and more obligations. The cost has run from $1,200 a few years ago to $1,800 in Duluth. This year I was told to cut down, and we are having a two-day meeting, practically, as you know. If we are to have meetings in other cities we have to put on a different type of meeting, because we have to bring in outsiders for attraction, and allow each one from $200 to $300 for traveling expenses and one thing or another. It soon counts up when you have two or three or four speakers.

We would like to see the commercial exhibits in the hands of the state office, so that we could apply that expense to the state meeting and make a better meeting. Dr. Loomis is here. If you want to know about how to organize a commercial exhibit, he can tell you. This, I believe, is his first experience. As I said, he did a fine job. He had more than he could take care of.

Dr. E. A. Loomis (Minneapolis): Mr. President, the committee feels that this ought to be handled by the state. As you say, each year a new committee gets hold of it and you do not get organized. For instance, we took hold of this in February. I believe we could have had twice as many exhibits if we had taken hold of it before the first of the year because they all make up their budgets around the first of the year. When you send out the letters they write back and say, "We would have taken space if we had known about it the first of the year."

If you treat these fellows well and keep track of them from year to year, it will work much better. This year there is going to be a surplus and it goes to the Hennepin County Society. It might just as well go to the State. The dentists had ninety exhibitors at their meeting, and we have about thirty. We could have had at least fifty or sixty, but we have to get more space, if this thing keeps on growing. But the committee is strongly in favor of having it handled by the state, and the local men can do whatever the state wants them to do and help out.

President Sogge: There is one motion before the house that the report of the Committee be accepted. Is there any further discussion? All in favor of that motion say "aye"; contrary. The motion is carried.

Dr. Locken: "5. That the Public Contact Program be continued as in the past and special emphasis directed toward: (1) Medical leadership in County Public Health Associations. (2) Constant contact with the Public Health Nurses Association. (3) Coöperation with the Minnesota Editorial Association. (4) Coöperation with the University Medical School."

President Sogge: What do you want to do with this recommendation?

Upon motion regularly made and seconded the recommendation was adopted.

Dr. Locken: "6. That in the policy toward medical legislation the Association, appreciative of the present high standard of medical statutes, ask no further immediate favors from the legislature except to continue the principles now established; that expenditures for legislative activities be budgeted and audited by the Council."

Dr. M. S. Nelson (Granite Falls): Inasmuch as we don't know what is going to develop, it seems to me the Legislative Committee should not be handicapped as to expense or in any way more than they have been handicapped in the past. If this is going to be any handicap to the Legislative Committee, it seems to me it should either be referred to the Council or laid on the table.

Dr. Boyer: The Association and the Legislative Committee have not contemplated any legislation since the Basic Science Bill was passed, though we can never tell when some new type of legislation may become necessary. Something may come up that will require active work on the part of the Legislative Committee two years hence. The chances are there won't be any need for legislation; we hope not. But owing to the fact that such a possibility exists, we ought to take that into consideration.

As to the matter of activity on the part of the Legislative Committee, that must exist. This recommendation in no way touches upon that. There is legislation that will need to be combated. So far as that is concerned, this resolution does not interfere. But there is the possibility that it would interfere with what might prove to be a need for active legislation. Therefore, it seems to me that we ought to insist upon that resolution or that recommendation being altered.

Dr. Wright: In your discussion, Dr. Locken, I think you put in the phrase "as far as possible." I think that is an excellent phrase to put in.

Dr. Locken: That is in the main discussion of the thing. It was left out of the summary.

Dr. Wright: That leaves it quite clear, I think.

Secretary Meyerding: Do you want to add those words?

Dr. Locken: Yes, after "statutes."

President Sogge: Read that sentence again.

Dr. Locken: "That in the policy toward medical legislation the Association, appreciative of the present high standard of medical statutes, as far as possible, asks no further immediate favors from the legislature except to continue the principles now established."

President Sogge: With that correction, have you any objection?

Dr. Nelson: With that change, I move its adoption.

The motion was regularly seconded, was put to a vote and carried.

Dr. Locken: "7. That toward the problem of finance the Association restrict its expenditures in both legislative and educational activities to a level that can be met with the present income."

Secretary Meyerding: Dr. Locken, I wonder if you could take out the word "present" and say "its income." Somebody might want to give us some money and we couldn't spend it. I have a scheme now whereby we may raise some money.

Dr. Locken: It was simply an expression that we maintain our organization on the present level of dues.

President Sogge: Will you correct that?

Dr. Locken: "With its income."

President Sogge: You have heard this report. What do you wish to do with it?

Dr. Coventry: I move its adoption.

The motion was regularly seconded, was put to a vote and carried.

Dr. Locken: "8. That the policy of developing a reserve fund from savings in the management of the Association be continued. That steps be taken to give prizes and scholarships, both undergraduate and graduate, to the students of the medical school to indicate the interest of the Association in medical education."

Dr. Coventry: I move its adoption.

The motion was regularly seconded.

Dr. F. J. Savage (St. Paul): This fund amounts to about $24,000, and there isn't any definite unanimity of opinion among the members of the Council as to what sum this should reach before various expenditures might be made from it. In order to clarify this resolution I move the following amendment: After the word "that" in the second sentence insert the words "when deemed feasible," so it will read: "That, when deemed feasible, steps be taken to give prizes and scholarships," etc. That will make it less compulsory on the part of the Council, if they didn't want to put in this small amount at the present time, to defer the establishment of the precedent.

The amendment was regularly seconded.

Dr. Wright: I should like to say that this resolution came from Hennepin County, and it came because of the question of reserve, how large a reserve fund we should have. I don't want to urge the thing, but inasmuch as that is one of the things that was most anxiously wished for in this resolution, I should like to have some expression of opinion as to what we should aim for in the accumulation of a reserve fund. It may not be definite, but I think we ought to crystallize our opinion, to some extent, on what we want. If the House of Delegates has any opinion about it, it would be interesting to know. I wouldn't want to urge it upon the House of Delegates, but my personal feeling is that we should set our reserve fund fairly high. I believe all organizations are recognized by their financial responsibility, and I believe a reserve fund put at $50,000, $100,000, or something of that kind, might be a good thing to shoot at.

Dr. W. A. Fansler (Minneapolis): I am a member of this Committee but the conclusions do not necessarily represent the feeling of each individual as an individual. One reason we did not set a definite amount on this thing was the fact that we couldn't agree upon it; also, there was a great deal of disagreement on the questionnaire we sent out. I think there was more difference of opinion on that than almost anything else. But speaking for myself as a Delegate, I feel we should have a definite reserve fund that we can rely upon. If we had a reserve fund, perhaps, at the start of $50,000, it would mean a reserve of $20 per member, and that isn't much for protection. We spend that much each year for insurance against malpractice. I quite agree that if there was a definite amount, it would have some influence with the legislative bodies and with other people too. I should like to make an amendment that we set $50,000 as the goal for a reserve fund, for forwarding the interests of the State Medical Association. I merely mention that amount so we can get some discussion and see what the reaction is.

Dr. Coventry: The gist of the argument is this: The second part of that paragraph is the most essential thing, whether you are going to use any of this money for scholarships and so forth, as the Committee has suggested. It is my notion, personally, that we should take steps to establish some relationship between the Society and the graduate body and university by offering prizes or something of that kind. That does not have to be $1,000 or $500 or anything of that kind. You can start to take steps even before you get the total amount of reserve brought up.

Dr. McDowell: You and I have to go home and explain to a lot of fellows what we are going to do with $50,000. They say, "We are paying too much dues." They are the kickers. You and I know that we ought to have some money in reserve in order to make a showing against our opponents in the legislature or against insurance companies or anybody else that want to buck us. But we have to take back to those fellows at home something definite as to what we have this reserve for.

Another thing is that you can use this money for scholarships and hope to get it back, which you probably will, but I just happened to talk with a man who runs a business college up at Fargo, whose son is studying medicine in Chicago. He was prouder than a peacock because his son had a key which he earned doing some research work at the University of Chicago, and he seemed prouder than if it had been a scholarship. I don't think that cost them very much money. You could give prizes that way and it would not cost you much. When you talk to the fellows at home about giving out money to help somebody else through school they holler about "who helped me through school?" They say, "We have too many doctors."

Dr. W. F. Braasch (Rochester): We might reassure the constituents that within the last few years very little has been added to the reserve fund. Almost every dollar of income has been necessary for expenditures. I do think that if we could have a reserve fund, without mentioning any exact figure, but a considerable amount, it would be an indication of power and we could use it for a whole lot of emergencies. I should like to see the day when we had an income from which our Secretary might be paid, or some special officer, or could take care of some special thing that would arise. In other words, it would certainly be for the best interests of the Association if we had a large fund back of us.

Dr. Wright: I wonder if that couldn't be amended by including the word "endowment" or "donation." Sometimes societies get money that way. I think it would be a good thing to make a statement about reserve even though they feel it should not be increased. I think it would be perfectly all right, if the Committee so feels, to say "we do not feel the reserve should be increased at the present time." What do you think of that?

Dr. McDowell: As I said before, I think we ought to have this reserve. If we can make some definite use of it, for research work or paying our officers, or something of that kind, we will ultimately cut down the dues, but we should have some idea of what we are going to use it for, for the fellows at home.

Dr. Ivar Sivertsen (Minneapolis): I might tell Dr. McDowell to bring home to his local society, and I think the balance of the members can bring it home to their societies, the fact that the chiropractors and osteopaths and other cults are paying from $200 to $300 a year during the legislative years for a fund to fight bills. If they can afford to pay that much money, it seems to me we can afford to pay $15 a year to the State Society for the help they give us in bringing about the legislation we need.

Dr. Workman: This increase in our Reserve Fund is due to the interest on the money. It isn't taken from our dues. It is the interest that is increasing our fund now.

President Sogge: We have an amendment to the original motion. That is the thing before the house.

Dr. Coventry: May I ask for a reading of the original resolution?

Dr. Locken: "That the policy of developing a reserve fund from savings in the management of the Association be continued. That steps be taken to give prizes and scholarships, both undergraduate and graduate, to the students of the medical school to indicate the interest of the Association in medical education."

The amendment was simply in the second sentence: "That, *when deemed feasible,* steps be taken to give prizes and scholarships."

President Sogge: You have heard the amendment. What do you wish to do with it? It was moved and seconded that the recommendation be so amended. All in favor of the amendment say "aye"; contrary. The "ayes" have it. Now the original motion.

Dr. Coventry: Who deems it feasible?

Dr. Locken: Who made the amendment? Let him explain what he had in mind.

President Sogge: Dr. Savage made the amendment.

Dr. Savage: This carries with it the fact that the Council is the only body with power to spend that money, unless it could be spent by orders of the House of Delegates. So this amendment means when the Council deems it feasible. It does not make it quite as mandatory as it reads at present.

President Sogge: We are on the original motion that we accept this recommendation. Is there any further discussion? All in favor of that signify by saying "aye"; contrary. The motion is carried.

Dr. Locken: "9. That the medical journal Minnesota Medicine continue its present policy of serving as an organ for scientific articles and association activities. The subject of economics should be left to the Editorial Committee."

President Sogge: You have heard this recommendation.

Dr. Braasch: I think that last conclusion is unfortunate in one way. While we are all proud of Minnesota Medicine and we are proud of the scientific standards they have maintained, we have a medical journal which is second to none, nevertheless, I think many of the members of the Association and I am sure most of the Delegates here are interested in subjects other than scientific medicine. I refer particularly to the subject of medical economics. There seems to be some confusion in regard to that. Medical economics does not necessarily mean financial aggrandizement as a recent editorial in Minnesota Medicine would suggest. It refers to a broader aspect, namely state medicine, insurance, medical insurance, contract practice. Many sociological changes in the practice of medicine are creeping in and developing rapidly. The only way the medical profession can insure its present enviable status is by concerted action in solving these intelligent questions. How can we solve these questions until we know about them? The only medium we have at our command is our medical journal. I think the pages ought to be open to the subject of medical economics and we ought to encourage, in fact we ought to pass a resolution, that the Board of Editors develop this to a greater extent. I believe as the resolution reads it would not do that. I, therefore, would like to amend the resolution as follows: It is the opinion of the House of Delegates that we commend the Board of Editors in their present policy toward the financial development of the Journal, that the pages be open to even a greater extent to the discussion and intelligent information concerning medical economics.

The motion was regularly seconded.

Dr. N. O. Pearce (Minneapolis): It seems to me the question of medical economics is one that should have more attention in the Journal. It should have more attention from the State Association. I am sorry more of you were not here last night when we presented statistics on the present situation in medical practice. I think it is very important that the State Medical Association at this time should set up an Economics Committee, a committee which will make a study of medical practice, medical conditions in the state, make an analysis of what the doctors in the state are earning and what they are going to have to compete with in the future.

There is a committee in existence known as the Committee of Fifty which was supported by funds from somewhere, I don't know where, possibly insurance companies. Anyway, this committee of fifty or sixty men, most of which are doctors but only a few representing organized medicine, is making a study of the high cost of medical care. They are not making this study from the standpoint of the earnings of the physician, particularly, but with the idea of presenting facts which are concerned with the high cost to the public for care when they are sick. We don't know what the final recommendation of this committee will be. They are not a practicing medical group. There are a great many doctors on that committee. Many of them are teachers or sociologists, and we have representation from our American Medical Association, not a large representation. I think Dr. West and others are really concerned with what recommendations may come out of this committee. Certainly, as has been said so many times, just around the corner there is a scheme, there is a plan for some sort of compulsory health insurance. This is a world-wide movement. It has the endorsement of various world-wide organizations. It has taken place and has become established in many of the leading countries of the world.

It seems to me that this Association here in Minnesota, regardless of what the American Medical Association is doing, regardless of what anyone else is doing, should prepare among ourselves for a close analysis of the report of the Committee of Fifty and all other conditions that have to do with the practice of medicine from an economic standpoint. We should have a committee with enough funds appropriated by the Council for the necessary clerical help to gather together all of the information. We should be making our own studies of these various types of panel medicine that are going on in European countries, so we may be prepared in the next year or two, when a move is on foot, to meet that move in an intelligent manner.

I don't know whether it would be appropriate to have another amendment asking for the appointment of such a committee. If it is, I should like to make such a motion.

Dr. Locken: The suggestion we made here was made because we first obtained the sentiment of the Editorial Committee. We found in preparing this report that it was very necessary to guide our suggestions carefully, because we found that the Council, the Legislative Committee and the Public Health Committee were rather sensitive to anything that might be inferred as a question of criticism of their present policies. So purely as a matter of courtesy to the Editorial Committee of Minnesota Medicine, which we feel has been doing a very fine piece of work, knowing their reaction, we felt we should leave that to their judgment rather than ask them to change their methods. I think in the manner of expression of the view of Dr. Braasch and Dr. Pearce, it would be a very fine thing if we carry out both of those suggestions and have such a committee.

President Sogge: Is there any objection to Dr. Pearce's amendment? I will entertain such an amendment.

Dr. Pearce: I move, Mr. President, that the House of Delegates authorize the Council of the State Medical Association to appoint a committee to be known as the Economics Committee, composed of five members, this committee to make a study of economic conditions (I won't describe it further than that) and that the Council be authorized to appropriate a reasonable sum of money for clerical and other help necessary to carry out the work of the committee.

President Sogge: Dr. Braasch, do you accept that amendment?

Dr. Braasch: I think that motion is out of order. I made an amendment to the motion for the adoption of this resolution.

President Sogge: We thought of getting it into one motion.

Dr. Braasch: I don't see how you can do that. This is a committee that has to do with medical economics, and I am making an amendment to the resolution.

President Sogge: I think the point is well taken. Let us have the amendment. Dr. Braasch, will you state it again?

Dr. Braasch: What was the last half of your resolution?

Dr. Locken: "The subject of economics should be left to the Editorial Committee."

Dr. Braasch: I move that it be amended to read: they be requested to open the pages of the Journal even more than they have in the past to the discussion and to the publication of articles dealing with medical economics.

President Sogge: That amendment was seconded. Is there any discussion? All in favor signify by saying "aye"; contrary. The motion is carried.

Let us consider Dr. Pearce's motion that a committee be appointed by the Council, known as the Economics Committee, and that the Council should be empowered to appropriate enough money for clerical work. Is there a second?

The motion was regularly seconded.

President Sogge: Is there any discussion? All in favor signify by saying "aye"; contrary. The motion is carried.

Dr. Wright: I should like to rise to a point of information. There has been a good deal of discussion about the House of Delegates appropriating money. I would like to know whether the House of Delegates has any right to appropriate a cent or not, without consent of the Council. The reason I ask that is this: The Trustees of the American Medical Association are the only ones who can appropriate money in the American Medical Association. The House of Delegates can't appropriate a cent without the consent of the Trustees. A bank can't appropriate money without the consent of the board of directors. The Council is our board of directors. Therefore, under our articles of incorporation, I don't believe we can possibly legally appropriate funds without the consent of the Council. I should like to know if there has been a legal question on that point.

Dr. Coventry: I would like to ask the speaker if the House has appropriated money. This motion was that the Council have the power to do it.

Dr. Wright: I am not questioning that. I think it should be understood that the House of Delegates have no power to appropriate funds without the permission and consent of the Council.

President Sogge: We probably are exceeding our power to a certain extent, but what we wanted to know is if the House of Delegates approve the action if the Council so does.

Dr. Locken: "10. That the question of combining the offices of Secretary and Treasurer be decided on the recommendation of the Coucil."

It is understood that if that change is made it is necessary to have an amendment to our Constitution.

President Sogge: Do I hear a motion on that?

Upon motion regularly made and seconded, the recommendation was adopted.

Dr. Locken: "11. That the present group of attorneys of the Association be retained."

Dr. Scofield: I move the adoption.

Dr. Coventry: The present group is Oppenheimer, Dickson, Hodgson Brown and Donnelly. It may not be the policy of the Councilors to employ these people. I don't know personally whether we should act upon such a resolution at this time. We may have some good reason in the Council why we want to change this. If the House of Delegates order us to do so, we are rather up against it. There may be good reason why we would want to change.

President Sogge: There is a motion that we accept this recommendation. You can vote it down or accept it as you want. Is there any further discussion?

Dr. M. W. Smith (Red Wing): Is that a recommendation? The Councilors can do as they please.

Dr. Coventry: The Council does not like to do things against the wishes of the House of Delegates.

Dr. McDowell: It seems to me that if we are going to have a Council of intelligent men and they are going to run this business for us, we ought to let them do much as the board of directors in a bank would do. We ought to give them a little power to change the attorneys if they want to. I think we ought to vote that down.

Dr. Locken: That was in the report merely because certain members of the Council asked the Committee, in the first place, to consider that recommendation. It is perfectly satisfactory to us to have it removed. We only have it in the report because we were asked to consider it.

Dr. Magney: How are the attorneys paid, on the basis of work they do?

President Sogge: Yes, the work they do.

Dr. Magney: Instead of specifying that we retain the present group of attorneys, say that we have attorneys representing us.

President Sogge: You have heard the motion. Is there any further discussion?

Dr. Smith: I move it be laid on the table.

The motion was regularly seconded.

President Sogge: All in favor of the motion to lay on the table say "aye"; contrary. The motion is carried.

I feel that this House of Delegates ought to give this Committee a vote of thanks for all the work they have done. They have surely worked well, and they have studied the questions. I feel we should incorporate in the record a vote of thanks to the Committee.

Dr. O. J. Hagen (Moorhead). I so move.

The motion was regularly seconded, was put to a vote and carried.

President Sogge: Election of officers. Who do you want for President for the ensuing year?

Dr. W. C. Carroll (St. Paul): I think there are very few societies in the country that can boast of so many prominent men as the Minnesota State Medical Association. Among them we have one of international reputation, a prolific writer in his chosen field. He has been president of the county society, the Southern Minnesota Medical Society, and chairman of his section in the American Medical Association. He has been a Delegate here on numerous occasions and is at present on the Council. I am sure that the mention of his name will be sufficient to place him in the office which has held so many prominent men.

I nominate Dr. Melvin S. Henderson of Rochester. (Applause.)

President Sogge: Are there any further nominations?

Dr. A. G. Schulze (St. Paul): I move that the nominations be closed and that the Secretary cast the unanimous ballot of this House of Delegates for Dr. Henderson of Rochester as our President-Elect.

The motion was regularly seconded, was put to a vote and carried.

Secretary Meyerding: The Secretary hereby casts the unanimous vote of the House of Delegates for Dr. Melvin S. Henderson as President for the ensuing year.

President Sogge: Who do you want for First Vice President?

Dr. Pearce: I would like to nominate Dr. Bert Adams of Hibbing.

The nomination was regularly seconded.

President Sogge: Are there any other nominations?

Dr. Coventry: I move that the nominations be closed and that the Secretary be instructed to cast a ballot for Dr. Adams.

The motion was regularly seconded, was put to a vote and carried.

Secretary Meyerding: The Secretary hereby casts the unanimous vote of the House of Delegates for Dr. Adams as First Vice President.

President Sogge: Second Vice President.

Dr. A. W. Adson (Rochester): I should like to nominate Dr. A. E. Hedback, Minneapolis, who is General Chairman of the Committee on Scientific Assembly as Second Vice President.

The motion was regularly seconded.

President Sogge: Are there any other nominations?

Dr. Adson: I move that the nominations be closed and the Secretary be instructed to cast the ballot.

The motion was regularly seconded, was put to a vote and carried.

Secretary Meyerding: I hereby cast the unanimous vote of the House of Delegates for Dr. Hedback as Second Vice President.

President Sogge: What about the Secretary?

Dr. Pearce: I move that the President cast the ballot for the present incumbent, Dr. Meyerding.

The motion was regularly seconded, was put to a vote and carried.

President Sogge: The President casts the ballot for Dr. Meyerding as Secretary for the ensuing year.

Who do you want for Treasurer?

Dr. W. A. Fansler (Minneapolis): We have a man that I think would make a good Treasurer. He has been on the Council for a number of years. He is familiar with the workings of the organization. I would like to nominate Dr. W. H. Condit, Minneapolis.

The nomination was regularly seconded.

Upon motion regularly made and seconded, the nominations were closed and the Secretary was instructed to cast the ballot for Dr. Condit.

President Sogge: We will instruct the Secretary to cast the ballot.

Secretary Meyerding: The Secretary casts the unanimous ballot of the House of Delegates for Dr. Condit as Treasurer for the ensuing year.

We want to announce that this is the largest House of Delegates meeting. Our records show there are 59 Delegates present out of 62. There are only three societies not represented. That is the largest we have ever had.

The total registration at this time is a little over 550, and we expect that it will be over 900 at the close of this meeting.

President Sogge: Councilors. Dr. Henderson is now President-Elect. We will have to have a Councilor from the First District.

Dr. Adson: The Rochester delegation would like to put in the name of Dr. H. Z. Giffin as candidate for the Council for the ensuing year.

PRESIDENT SOGGE: Are there any further nominations from the First District?

DR. BRAASCH: I move the nominations be closed and the Secretary cast the ballot.

The motion was regularly seconded, was put to a vote and carried.

SECRETARY MEYERDING: I hereby cast the unanimous ballot of the House of Delegates for Dr. H. Z. Giffin as Councilor for the First District.

PRESIDENT SOGGE: Third District. Dr. Workman is the present Councilor.

DR. BOLEYN: I nominate Dr. Workman.

Upon motion regularly made and seconded, nominations were closed and the Secretary was instructed to cast the ballot.

SECRETARY MEYERDING: I hereby cast the unanimous ballot of the House of Delegates for Dr. Workman as Councilor for the Third District.

PRESIDENT SOGGE: The next is the Fifth District. Dr. Savage is the present Councilor.

DR. BOLEYN: I nominate Dr. Savage as Councilor for the Fifth District.

DR. BRAASCH: I take pleasure in seconding that nomination.

PRESIDENT SOGGE: Are there any further nominations?

Upon motion regularly made and seconded, nominations were closed and the Secretary was instructed to cast the ballot.

SECRETARY MEYERDING: I hereby cast the unanimous ballot of the House of Delegates for Dr. Savage as Councilor for the Fifth District.

PRESIDENT SOGGE: Seventh District. W. W. Will, Bertha.

DR. PEARCE: I nominate Dr. Will.

DR. MCDOWELL: I move the nominations be closed and the Secretary cast the ballot.

The motion was regularly seconded, was put to a vote and carried.

SECRETARY MEYERDING: I hereby cast the unanimous ballot of the House of Delegates for Dr. Will as Councilor for the Seventh District.

PRESIDENT SOGGE: Delegates to the American Medical Association. The Council recommended the nomination of Dr. C. B. Wright as Delegate and Dr. J. T. Christison as Alternate. Are there any other nominations?

DR. SCOFIELD: I move that the nominations of the Council be accepted and the Secretary cast the ballot.

The motion was regularly seconded, was put to a vote and carried.

SECRETARY MEYERDING: The Secretary casts the unanimous ballot for Dr. C. B. Wright as Delegate and Dr. J. T. Christison as Alternate to the American Medicine Association.

PRESIDENT SOGGE: Meeting place for next year.

DR. CARROLL: I have letters from the Mayor and the Secretary of the St. Paul Association inviting the State Association to meet in St. Paul in 1932.

DR. BRAASCH: I take great pleasure in seconding that invitation. It was the intention of those of us from Rochester to invite this Association to meet there next year. However, we would defer to the wishes of St. Paul, knowing that they have started their campaign. However, we hope this Association will see fit to come our way in 1933.

PRESIDENT SOGGE: You have heard this invitation to meet in St. Paul next year. Are there any other invitations?

DR. KLAVENESS: I move it be accepted.

The motion was regularly seconded.

PRESIDENT SOGGE: You have heard the motion. All in favor of meeting in St. Paul next year say "aye"; contrary. The motion is carried.

SECRETARY MEYERDING: Last year the House of Delegates passed a resolution, or at least it was its opinion that we do not have our House of Delegates session during the scientific meetings. We have tried to do this. We had the House of Delegates meet last night. There has been criticism on the meeting. We would like to do what the Delegates want. If you will discuss that a minute, we would appreciate it very much. What time of the day do you want to meet and at what hour? Would you like to meet during the scientific sessions or go back to the old way, meeting on Monday afternoon at one-thirty or two o'clock? We had medical economics in the evenings, and the next day the scientific program commenced. If you will make some expression so we can work upon it, we will appreciate it very much.

DR. ROBBINS: I suggested last year that we meet the day before the scientific meeting so we could finish this session in the afternoon instead of the evening, and cover all of it.

PRESIDENT SOGGE: I will appoint the following committee to present the President-Elect to the House of Delegates: Dr. E. S. Boleyn, Stillwater; Dr. M. S. Nelson, Granite Falls; Dr. S. A. Slater, Worthington.

Let us have your expression on the subject brought up by the Secretary.

DR. ADAMS: The meeting last night was ideal. We don't have to break up a whole day. I was able to do some of my work yesterday morning. I don't see how that can be improved upon.

SECRETARY MEYERDING: We wanted to have it on Sunday but somebody said that wasn't good form, somebody might criticize us for working on Sunday. We discontinued the idea of Sunday, and Monday night seemed the best plan under the circumstances.

DR. WRIGHT: Certainly from the standpoint of attendance and interest, I think this has been the most interesting meeting we have had in the House of Delegates. I think that matter should be left to the Council. As far as Sunday is concerned, I am not a particularly scrupulous religious adherent or churchgoer, but I feel it is the only day a man has to give to his family, and I feel that to hold a meeting of this kind on Sunday would be a little bit out of step.

The audience rose and applauded as President-Elect Henderson was escorted to the platform.

PRESIDENT-ELECT HENDERSON: Mr. President and Members of the House of Delegates: Needless to say, this is a proud moment for me. I heard rumors that it might happen so I thought I had better get out for a few minutes and give you a chance to say what you wanted to say about me.

A thing of this kind comes to a man only once in a lifetime, and I wonder whether it means that I have passed the noon of my surgical career and am tripping down the other side. I know that while I am very proud, I am also very humble. I realize that it is a tribute not only to myself but to my good friends with whom I have worked for many years, and I take pride in the fact that I am to shed a little light on them in a small way.

The State Association, of course, has grown. Its activities have varied, and the traditions and all that are back of the Association are wonderful. Minnesota has been in the vanguard of progress in medical work and scientific work in the United States in the past, and now they are holding that position, advancing along the lines of economic medicine.

I don't want to take any more of your time. There is much I could say and much I would like to say. All that I can say is that I am very proud and will do all I can to fulfill this high office and be of service. (Applause.)

President Sogge: Let us go back to where we were, the time of holding the meeting next year. Let us have a motion.

Dr. B. I. Saliterman (Janesville): I move that the time be left to the Council.

The motion was regularly seconded, was put to a vote and carried.

President Sogge: We have some resolutions.

We want to offer a resolution of thanks to the Hennepin County Medical Society for its fine work in entertaining the Association, to the Nicollet Hotel and its management, to the Minneapolis Civic and Commerce Association, to the Minneapolis Journal, Tribune and Star.

President Sogge: You have heard these resolutions.

Dr. Adson: I move they be adopted and that a committee be appointed to draft the resolutions.

The motion was regularly seconded, was put to a vote and carried.

President Sogge: I will appoint as the Resolutions Committee: O. J. Hagen, Chairman, Moorhead; W. A. Piper, Mountain Lake; C. L. Scofield, Benson.

I will ask Dr. Braasch and Dr. Boyer to present the newly elected officers to the Association tomorrow morning at ten o'clock.

I will have to ask your pardon for having rushed the business so fast but I felt it was absolutely necessary because we wanted to get to the clinics.

Is there any new business, or anything anybody wants to bring before the body?

I want to say I feel very grateful to you for the splendid way in which you have transacted business here this afternoon. A motion to adjourn is in order.

Upon motion regularly made and seconded the meeting adjourned at one-fifteen o'clock.

SCIENTIFIC PROGRAM

The scientific program was presented as published in the April, 1931, number of Minnesota Medicine with the following changes:

Dr. Arthur E. Smith, Minneapolis, presented a paper Wednesday morning entitled "Impairment of Vision Following Head Injuries."

Dr. C. A. Neumann was not present to present his paper on "Fractures of the Wrist."

Wednesday afternoon Dr. S. A. Slater, Worthington, made the announcement that the prize offered by the Southern Minnesota Medical Association for the best scientific exhibit displayed at the State meeting had been awarded to Dr. W. P. Herbst, Minneapolis, and honorable mention given to Dr. R. K. Ghormley, Rochester. The medal was formally presented August 24, 1931 at the annual meeting of the Southern Minnesota Medical Association.

The papers presented will for the most part be published in subsequent issues of Minnesota Medicine.

CARDIOLOGY AND THE GENERAL PRACTITIONER*

Drew Luten, M.D.
Saint Louis, Missouri

ABNORMAL circulatory phenomena occupy rather a large part of the general practitioner's time. In some cases they are his chief concern; in many more they arrest his attention even though his primary interest may be otherwise directed. For some of them he finds ready explanation. Others present problems of greater difficulty. He is sometimes confused by apparent contradictions. A man rejected for life insurance lives long in good health while another recently accepted without question dies suddenly of coronary occlusion. A patient with signs of serious heart disease stands an emergency operation well, while another with little evidence of circulatory disorder suffers collapse. A woman yet in her twenties dies of rheumatic heart disease while another in her fifties who has had well defined mitral disease for forty years sails for Europe on a pleasure trip. The practitioner finds bradycardia in one patient with brain tumor, in another with heart block. Extreme tachycardia accompanied by auricular fibrillation he encounters in patients with thyrotoxicosis who later exhibit no abnormal cardiac signs, and also in patients about to die of heart failure. He observes regularity of heart action without acceleration and without murmurs in patients on their death beds and he sees men doing hard work who exhibit systolic murmurs and whose heart beats rapidly. In one case certain cardiac signs present no special problem, in another grave questions await their proper interpretation.

In explaining such apparent contradictions certain physiological principles must be kept in mind. Not only is the circulation vital to all tissues of the body but it is also the chief means of correlating the activities of the various parts. Only through it do the several organs function as members of a single body. In health the demands upon the circulatory system are constantly changing and in order to meet these demands it responds easily and quickly to many and varied influences. This lability of the circulation is especially valuable in disease where an observed phenomenon is often the resultant of many factors. Thus it is that pathological processes widely different in character may be accompanied by circulatory phenomena quite similar in kind, while different signs may result from disorders closely related in origin.

In every instance circulatory signs and symptoms must be considered in their relationship to other aspects of the case. Abnormal circulatory manifestations cannot be regarded as independent or as isolated phenomena. This being true, therapeutic procedures in most instances should not be directed primarily against them. It is rather to the underlying pathological process responsible for the observed effect that direct consideration should be given. Exceptions occur. In some instances the primary process cannot be discovered. Secondary disease processes in general may themselves be attended with danger, with pain, or with annoyance. Under any of these circumstances they must be directly treated unless the cause may be readily removed or controlled. But such exceptions should not divert us from general principles nor distort our perspective. It is the purpose of this paper to apply these fundamental conceptions to certain abnormalities of the circulation commonly encountered in general practice, particularly to certain abnormalities of heart rate and of heart rhythm.

---

*Read before the Minnesota State Medical Association, Minneapolis, May 6, 1931.

Simple Tachycardia.—Simple tachycardia in many instances represents an adjustment of the circulation to pathological processes and should not receive special therapeutic consideration. Therapy in such cases obviously should be directed not toward slowing the heart, but toward mitigating the cause of tachycardia. Mere slowing may indeed upon occasion be harmful. The initiation of direct measures to lessen the heart rate in hemorrhage, in pneumonia, in fright or in exophthalmic goiter would appear as illogical as the taking of similar means to slow the respiratory rate in the same circumstances; as illogical as trying to slow it after exercise.

The assumption is widespread that tachycardia itself is attended by serious danger if long continued; that the heart cannot long withstand rapid beating. This conception has received an emphasis which appears to be unwarranted. The heart is physiologically adapted to rapid action. Increase in rate *per se* does impose added burden, but a normal heart bears the burden well. Furthermore, compensatory adjustments usually supervene. Even a diseased heart usually appears to suffer little impairment of function from tachycardia of considerable extent, provided the muscle is activated in normal fashion, *i.e.*, provided the tachycardia originates at the normal pacemaker. In a diseased heart obviously the danger of fatigue from tachycardia may be enhanced, but even in such cases compensatory adjustments in stroke output and in vascular tension usually relieve the heart of this added danger. In many instances, indeed, the accelerated action itself appears to be a compensatory adjustment, tachycardia representing the effect of circulatory impairment, not its cause. Surely the chief indication of therapy in such cases should be the protection of the heart from further danger, not an unphysiological adaption to injury already received.

Not only is it inadvisable, in many instances, to slow the rate in simple tachycardia, but in adults it is rarely possible by therapeutic means to do so. In therapeutic dosage digitalis rarely, if ever, in adults causes slowing of consequence by direct action upon the cardio—inhibitory apparatus. The physician who pushes digitalis in such an attempt, even if slowing be desirable, subjects his patient to the serious danger of digitalis intoxication.

Abnormal Rhythms.—Abnormalities of cardiac mechanism in general have been given a prominence altogether out of proportion to their importance. In most instances the principles of treatment and the management of the patient are not influenced by their presence or absence. Certain exceptions to this rule will be noted below. One might say that cardiology after emerging from the age of murmurs and before reaching the light of the functional era was for a decade or more confused in the dark period of abnormal rhythms. But it is emerging from the dark age and is beginning to lay aside some of the terror inspired by the mythology of abnormal rhythms.

Upon occasion, it is true, a patient's heart behaves as if under the spell of an occult influence, and all effort to exorcise the demon appears to be of no avail. Such visitations are comparatively rare. Better understanding has taught us that, as a rule, abnormal rhythms are not fearsome, and upon occasion are indeed quite friendly. In most instances not only is the general plan of treatment unaffected by the presence of such a disorder, but even the disordered rhythm itself demands no special therapy. It is properly ignored. Not infrequently, on the other hand, the occurrence of an abnormal rhythm, far from being inspired by an evil spirit to confuse us, proves but a friendly warning, a sign to point away from danger into the way of better treatment. Instead of trying to do away with the signal, we should, rather, accept its generous warning and lend our effort to overcome the danger it helps us recognize. After we have succeeded in doing this, the portent often vanishes only to reappear, perhaps, as danger is approached again. It thus becomes a useful gauge of proper therapy.

Auricular Fibrillation.—These considerations apply with special force to auricular fibrillation. Most patients with this disorder need treatment. So do most patients with fever and most patients with abnormal blood pictures. But usually it is better therapy to direct treatment against the cause of the fever or of the blood dyscrasia than to try blindly to change the temperature chart or the blood count by any means available. And even though the thoughtful physician gives much attention to these charts, finding them invaluable as guides, he still remembers that the object of his therapy is not a certain level of temperature or of blood, but a certain therapeutic result indicated by the chart he studies.

And so it is with auricular fibrillation. The great addition to our knowledge afforded by study of auricular fiibrillation and its graphic registration has so impressed medical practice that this disorder itself too often assumes chief place in therapy. Although exceptions occur, in the vast majority of cases it is not the disordered mechanism that needs treatment, but the disease process producing the abnormal rhythm. Treatment of this differs in different cases, the course of the auricular fibrillation being merely incidental. Rarely should it receive special treatment. The following examples are illustrative:

A patient after operation for toxic adenoma develops auricular fibrillation with tachycardia. The presence of the fibrillation alters the general aspect of the case very little, but fortunately it does make the picture of the "crisis" more distinct, thus defining more clearly the indication for iodine or other measures to meet it. Cause and effect must not be confused. The primary consideration in treatment must be the crisis, not some particular manifestation of the toxic effect.

A patient with rheumatism receives a specific vaccine, after which rise of temperature and auricular fibrillation develop. The auricular fibrillation is an incident in the reaction to excessive vaccine therapy, not the cause of it. Under appropriate treatment the reaction subsides, the abnormal rhythm disappearing along with other manifestations of it.

A patient with heart failure and auricular fibrillation receives digitalis. So do patients with heart failure without auricular fibrillation. Treatment is the same in both cases, the auricular fibrillation constituting no indication for special therapy. The presence of fibrillation in such cases may furnish a valuable guide to digitalis dosage, the heart rate usually being an index, to some extent at least, of the efficacy of the drug. But the indication for digitalis in heart failure, let it be remembered, is not modified by the presence or absence of fibrillation. Auricular fibrillation *per se* is not an indication for digitalis.

During the course of pneumonia the occurrence of auricular fibrillation is not unusual. Recent study of a large series of cases over a two year period shows that the administration of digitalis was accompanied by increased mortality in those patients with auricular fibrillation as well as in those with normal mechanism. Since fibrillation in such cases must be regarded as an expression of toxemia, this result would appear to demand no special explanation.

Although as a rule auricular fibrillation constitutes no indication for special therapy, exceptions occur. Great prominence has been given to the notion that the extreme tachycardia which sometimes results from this disorder may upon occasion be the source of great danger apart from other aspects of the case and demand special treatment not otherwise indicated. It would appear that this conception practically limits such special therapy to quinidine, and confines its employment under such circumstances to cases without heart failure. For surely in cases of this sort associated with heart failure digitalis is indicated irrespectively of the fibrillation and irrespectively of the tachycardia, and could not, therefore, be regarded as a special measure. Quinidine, furthermore, as a rule, is contraindicated in heart failure. In those cases of auricular fibrillation with excessive tachycardia unassociated with heart failure, on the other hand, due to toxemia or other cause, digitalis rarely is very effective, and may, indeed, be a source of danger. If this conception of the life-saving effect of quinidine is indeed correct, the occasion for its employment confronts the practitioner but rarely, and it, too, would appear to be not devoid of danger.

More commonly, cases of auricular fibrillation in which special therapy is indicated appear to fall into the other category, *i.e.*, that group of cases in which the disorder constitutes not an element of danger but a source of annoyance. In cases of this group in which the fibrillation cannot readily be eliminated by removal of the cause, and which present no contraindication to the administration of quinidine, this drug upon occasion may be employed with good results. It must be remembered, however, that cases of auricular fibrillation falling into this group constitute but a small proportion of total cases.

Extra Systoles.—In general, what has been said regarding auricular fibrillation applies also to extra systoles. In most instances patients exhibiting such interruptions to regular heart action should be treated precisely as they would be did the heart beat rhythmically. If the primary cause can be discovered, it should receive principal, if not entire, consideration. Toxemia must be combatted, infection removed, nervousness allayed. Tobacco may have to be eliminated, gastro-intestinal disorders corrected. Many patients are unaware of their occurrence. It would sometimes be better if this ignorance extended also to their medical advisors. But these disorders, too, upon occasion are helpful. They may suggest greater detail in examination or in history taking, or may demand closer consideration to therapeutic measures already in use.

Like auricular fibrillation they may demand special treatment. Occasion for this arises not from any danger inherent in the arrhythmia, but from the annoyance produced by it. A rather large proportion of those who are aware of extra systoles are greatly perturbed or annoyed by them. Strychnine is the drug of choice. In doses of 1/60 to 1/40 of a grain three times a day it stops the occurrence of extra systoles in many instances. The addition of small doses of quinine and of one of the barbituric acid derivatives frequently appears to be of value. Quinidine is often useful.

Heart Block.—Heart block is an expression of myocardial injury, an index of damage. In those cases in which the myocardial lesion results from infection or other acute process, removal of the cause usually results in restoration of function to the conducting tissue. The heart needs no special treatment, nor is special treatment often effective in removing the block. The patient needs careful management in an illness of such severity whether the conduction of impulses from auricle to ventricle is accomplished or not.

In chronic cases the prospect for recovery of conduction is poor with or without special treatment. The pathological process responsible for the block is rarely modified enough to restore conductivity. It is usually an index of grave injury to the myocardium and on that account rather than because of the bradycardia it lends gravity to prognosis. In these cases, too, the abnormal rhythm usually should be ignored in treatment. Tinkering is often dangerous.

The presence of Adams-Stokes attacks alters the situation. The danger here lies not simply in the failure of a-v conduction. The critical nature of the seizures demands the employment of measures offering any prospect of relief. Barium chloride in the interval, epinepherine during the attack, have been productive of good results.

Paroxysmal Tachycardia. — Paroxysms of tachycardia more commonly than other abnormalities of rhythm may demand special therapeutic measures. From their very nature, however, such paroxysms, whether auricular fibrillation, auricular flutter, auricular or ventricular tachycardia usually end spontaneously. Except in those cases in which the ventricular muscle parts are activated in abnormal sequence (ventricular tachycardia), there is rarely evidence of deficient circulation even with attacks of relatively long duration. And even in these cases the prognosis, as a general rule, is good so far as the particular attack is concerned. Necessity for special treatment, therefore, in paroxysms of tachycardia is the exception rather than the rule. These attacks may occur in patients without other cardiac abnormality, while upon occasion the cardiac lesion is so grave that life or death may depend upon the measures employed. The danger of doing too much is often as great as that of doing too little. The necessity of "doing something" may not be as urgent as the obligation of doing nothing harmful. Under such circumstances surely the thoughtful physician, whether general practitioner or specialist, would choose the company of those who tread with fear rather than rush into ill considered therapy. The indication for treatment in the vast majority of cases consists not in any danger from the attack but in the discomfort and perturbation produced by it. The patient should be put at rest, and sedatives or opiates administered as indicated. Not the least of quieting measures may be the reassurance which in most instances can be truthfully given. Differentiation, while frequently accomplished at the bedside, may be impossible without instrumental means. Pressure over the carotid sheath may be not only an important procedure in differential diagnosis but in paroxysms of regular auricular type it may be effective also in stopping the attack.

After a reasonable time if the attack does not end spontaneously, and if carotid pressure has been ineffective, special measures may be employed. The precise treatment may depend upon the type of paroxysm, and upon the circumstances of its occurrence. Extended discussion of the use of quinidine and of digitalis in the various types of tachycardia occurring in paroxysms would require space beyond the limit of this paper. In many instances these drugs control or stop such disorders. Upon other occasions it is unnecessary or unwise to use them. Rarely can the employment of either be regarded as an emergency measure.

In these disorders of rate and of rhythm, as well as in cardiac disorders generally, a complete history and a general examination are of more value in determining treatment than examination of the heart; in the examination, physical signs are of more value than graphic records. The following case well illustrates this rule, even though it constitutes an exaggerated example. A few days after operation a patient suddenly was seized with a paroxysm of tachycardia. The electrocardiogram showed ventricular complexes occurring regularly, but no one who examined the record felt confident of a precise electrocardiographic diagnosis. A second record, obtained a few hours later, in places showed ventricular complexes occurring regularly, in other places irregularly. Digitalis was ordered, and after this quinidine. The paroxysm soon ended. At no time had evidences of circulatory insufficiency been apparent. Later it was discovered that for twenty years the patient had been subject to frequent attacks of rapid heart action, in only a few of which had a physician been called. The attacks had always ended spontaneously, sedatives having been administered upon only a few occasions.

SUMMARY

Simple tachycardia frequently represents a compensatory adjustment of the circulation. When primary, compensatory adjustments usually follow it. Direct measures to slow the rate are rarely indicated and are rarely successful when tried.

Abnormal rhythms in the vast majority of instances require no special therapeutic measures. Some of them frequently are valuable hints in diagnosis and useful guides in therapy. They call for general examination and treatment, not merely for examination of the heart and cardiac drugs. The abnormal rhythm itself is rarely dangerous; it is frequently annoying. Special treatment, therefore, when indicated, is rarely an emergency measure. In most instances a complete history is more important than a complete cardiac examination.

PRENATAL CARE AND THE CAREFUL CONDUCT OF DELIVERY*

Martin C. Bergheim, M.D.
Hawley, Minnesota

In 1923 I read a paper before this association entitled: "Obstetrics and the General Practitioner." In that paper I emphasized the value of prenatal care. I brought out the fact that only 15 per cent of my obstetrical cases were reporting for such care. Furthermore, I stressed the point that it was the duty of every physician, doing obstetrical work, to educate the public that it might see the great value of prenatal care for the expectant mother and her child.

In 1929, in discussing a paper presented at the annual meeting of the State Association, I mentioned the fact that a careful review of my obstetrical cases showed that those coming in for prenatal care had in six years increased from 15 per cent to 83 per cent. And today I find that during the two years that have elapsed since May, 1929, 90 per cent of all obstetrical cases delivered by me have appeared once or oftener for prenatal care; and over 50 per cent of these reported before the end of the fourth month. I have found, therefore, (1) that it is possible for the doctor in general practice, and in the rural community, to do prenatal work; (2) that it is possible by persistant and conscientious effort, to teach the mothers the value of prenatal care; (3) I have found that expectant mothers can be taught to come regularly for prenatal care, even from the very early months of gestation.

When expectant mothers know that the doctor is willing to give them care during pregnancy, they will come from the remotest corners. Through social workers, county nurses, through newspapers and publications of the State Board of Health, and the Department of Labor, at Washington, the public of today has gradually come to know a great deal about prenatal care and its important bearing on the health and life of both the mother and her infant. Expectant mothers will go to the doctor who will give them such care. The doctor who is not willing to give prenatal care, has no right to expect to be called to the obstetrical case at the time of delivery.

I charge a reasonable price for my obstetrical cases, but make no extra charge for prenatal care given at the office. The cost, therefore, to the patient, is the same whether she comes in for prenatal care or not. It is a little difficult to teach these patients not to come in on Sundays and holidays, and after office hours at night. At one time I used to make a small charge for each call, if the patient came on "the day of rest," or at night. But now I make that a part of "that second mile," and smile in so doing.

Careful records must be kept of all obstetrical cases. I have a record card, six by eight inches, folded in the middle, printed especially for my obstetrical cases. Any size card, however, will do. The first prenatal call includes a complete physical examination as well as a past history of the patient. This first call will require twenty or thirty minutes. Subsequent calls will require only five or ten minutes of the doctor's time. And, if necessary, the well trained nurse can do most of the routine examination at these subsequent calls.

At the time of the first call careful pelvic measurements are made. The heart, lungs, kidneys, and the breasts are examined. The blood pressure is recorded. The mouth and throat are examined for possible foci of infection. These days, especially in primiparas, it is important to note the general nutrition, and to examine the lungs carefully, because of the high incidence of tuberculosis among young women. The general health of the patient must be considered. Malnourishment must be corrected. Many young women of today have highly sensitive nervous systems from various causes, and consequently we find among them many nervous and mental problems when they become pregnant. These neurotics are very often exceedingly hard to manage. They constitute one of the difficult, as well as one of the unpleasant problems, that a doctor has to deal with in doing prenatal work. They are worried, they did not want to become pregnant in many cases, they are afraid of pregnancy. The big majority of cases of vomiting of pregnancy are neurotic in origin and very seldom toxic. Often these patients vomit incessantly and clamor for the doctor to terminate the pregnancy. At times they must be hospitalized and isolated. Usually, however, they ultimately respond to the proper treatment. And one must always be alert to distinguish between the neurotic and the toxic types of vomiting.

---

*Presented before the annual meeting of the Minnesota State Medical Association, Minneapolis, May 5, 1931.

During the first seven months, if everything is normal, the patient need not report more than once a month. But during the eight and ninth months, she must report every two weeks. If any abnormality develops, the patient must report more frequently, and if a grave condition threatens, the patient is seen at her home or she may be hospitalized according to the gravity of the condition.

Even the very busy physician can afford to spend five or ten minutes a month or twice a month, to give the necessary prenatal care to his obstetrical cases. As a routine at the regular visits, the kidneys, the heart, and the blood pressure are examined. The general condition of the patient is observed, and any conditions, like "heart-burn," constipation, headache, puffiness of the eye-lids and feet, varicose veins of the legs and feet, are observed and corrected. Anything that points to beginning toxemia is noted and "nipped in the bud." Thus serious toxemias can be prevented. Toward the end of pregnancy the position of the child is noted. In general, the object of prenatal care is to bring the mother and the child safe and sound up to the time of delivery, and with as little discomfort, worry, and grief to the mother as possible. And when this has been accomplished, the whole battle of child bearing is more than half over. When labor sets in, the doctor knows his case, and the mother and her family know the doctor. Under these circumstances, the mother does not go into labor frightened and uncertain as to the outcome.

What are the results of prenatal care? Prenatal care saves the lives of mothers and infants. In the United States at large, there has been little, if any, reduction in the maternal mortality rate during the past fifteen or twenty years. If such a reduction comes, it must come through proper education of the public, proper prenatal care, and proper care of the mother during the delivery. There are many doctors in Minnesota who are training their patients to report for prenatal care, and by such care the maternal as well as the infant mortality rate, and the morbidity rate, are being cut down materially.

In California in 1920 the maternal mortality rate per thousand total births (including stillbirths) was 6.8. As a result of prenatal care in that State the maternal rate has been cut to 5.1 per thousand total births, a saving of almost two hundred mothers in that state alone.

According to the department of health in New York City the death rate among pregnant women who had the proper prenatal care was only one half as high as it was among those who had no such care.

In Kentucky, the prenatal clinic of the Louisville City Hospital has published some interesting statistics on the value of prenatal care. During a five year period ending in 1928 there were 3,217 deliveries. Of these, 2,061 attended the prenatal clinic, while 1,156 had received no prenatal care. In the first group there were only six deaths, or 2.91 deaths per thousand. Of the 1,156 who received no prenatal care twenty-six died, a rate of 22.4 per thousand deliveries. Over 3 per cent of those with no prenatal care developed eclampsia and ten died, while only a little over 0.5 per cent of those with proper prenatal care developed eclampsia and none of these ended fatally.

A report of the demonstration made by the Commonwealth Fund, shows the great value of preventive medicine in the field of prenatal care. The figures taken from four typical American communities, (Fargo, North Dakota; Rutherford County, Tennessee; Marion County, Oregon; Clark County, Georgia), show that the "Maternal death rate, still-births, and infant mortality under one month of age, were double in the group that received no prenatal care."

I take the liberty of quoting from an article by Doctor Polak of Brooklyn. He says, "In Brooklyn in the district influenced by our prenatal Clinic not only has the mortality in eclampsia been lowered, but severe eclampsia is an exception." . . . "This we attribute to continuous prenatal propaganda." This same authority gives the maternal death rate per thousand in a series of 12,066 cases, which were divided among five different hospitals and teaching units. All of these patients received prenatal care and good care during delivery. The average maternal death rate for the whole series was 3.5 per thousand, while the rate for the city at large was twice that high.

If we who do obstetrical work can cut the maternal mortality rate down from 6.2 which it is in the United States today, to 3.5 as has been done in these teaching clinics in Brooklyn, we would by so doing save annually seven thousand mothers.

True we cannot reduce the death rate to nil, because of the difficult cases that will develop, and because of miscarriages, abortions, poor health, improper hygiene, etc., but we can cut the death rate in two. What has been of such great benefit to individual communities will be of equally great benefit to the State of Minnesota and to the country at large.

Originally I was supposed to speak on prenatal care only. But, I added a coda to my subject, namely: "The Conduct of Labor." This was done because I wish to bring out one or two points in this connection.

In the rural districts, as well as in some homes in the city, the environment is often very unfavorable for the proper conduct of labor. The doctor and his nurse may do all in their power to carry out good technic during the delivery, but the hygienic environment as well as the type of intelligence and the conduct of the patient and the attendants may be decidedly against them. But, however unfavorable the environment one thing is certain, and that is this: If at the time of delivery one resorts to external abdominal examinations and rectal examinations only, one is not introducing any of the infectious material that surrounds the patient, into the parturient canal. I always keep this in mind that the vaginal secretions are almost always sterile, and, furthermore, that the vaginal flow is always outward. The only thing that goes in is the examining finger of the doctor. And if during delivery he makes no vaginal examinations he can rest assured that he has not introduced any infectious organisms.

The doctor in general practice must care for cases of virulent infection of every sort, and no matter how careful he may be, virulent organisms cannot be completely scrubbed from the hands. Sterile gloves should be carefully put on, rectal examinations should be made, and vaginal examinations resorted to only when absolutely necessary.

In an exhaustive article by Holmes, Mussey, and Adair, we read this statement regarding puerperal infection: "The source of infection in connection with child bearing may be considered as endogenous and exogenous. Endogenous infection may be largely ignored. Practically all puerperal infection may be regarded as contact infection and therefore as contagion."

I take the liberty of quoting from an article by Doctor Litzenberg: "The two principal causes of maternal mortality are infection and eclampsia, both almost wholly preventable." . . . "Over eleven thousand deaths each year are due to these causes." . . . "By application of the simple requirements of prenatal care and asepsis at delivery, thousands of these women need not have died."

In teaching the importance of prenatal work and the careful conduct of labor where shall we start? The public is willing to learn, but how can the public properly learn unless there is someone to teach? The responsibility rests first and foremost with the physicians. In any phase of medicine where the physicians are in the forefront and where they are doing their full duty the state and federal governments will not step in. It is when we fail in our vigilance that outside factors are ready to enter. It is possible for the doctor to do conscientious prenatal work whether he be located in the city or in the rural community. It is possible by persistant effort to teach the public the value of prenatal care. And it is possible to train the pregnant mothers to come and to come early in pregnancy. The doctor must learn first in order that he may teach the public. And the doctor must be willing to spend both time and energy in teaching the public.

The instruction at the medical schools, and the internships must teach the medical students the importance of the careful conduct of delivery under every circumstance. It is impossible for most medical schools to give each and every student the practical training in delivering obstetrical cases that he should have. Such practical training should for the most part come during the internship. An obstetrical service during ones internship where one is required to care for and deliver a large number of normal cases as well as a certain number of abnormal cases should be required. The medical schools are giving splendid courses in obstetrics, yet most of the real practical work must come during the hospital service. Not so many years ago when I took my intern work I spent four months on the obstetrical service in a large hospital. Three hundred and eighty-six patients were delivered during those months, many of them abnormal cases. I delivered any number of normal cases, but it was only after I got into private practice, when I had no staff member at my side to guide me, that I applied a pair of forceps for the first time, or did a version, or a breech delivery. In my first forceps case after I began private practice nature was very kind and let both the mother and the child live, but I trembled and "sweat blood" during the operation, and worried for days afterwards.

I have no large series of cases to draw from, and I have very little right as yet to quote any figures or draw any conclusions. I have, however, records of 1,342 cases. Among these I have had only one maternal death, and this was due to influenza contracted before delivery. There have been no cesarean sections; only one mutilation operation—this a case of an anencephelon. I have had only four cases of eclampsia, each developing only one or two convulsions, and I have never had to do a therapeutic abortion. I have, indeed, been fortunate. "My lines have fallen in pleasant places." But, if I have had a low mortality rate heretofore, in this small series, that is no guarantee that I will not lose a mother tomorrow, or next month, or two or three mothers by a year from now. But this I hope, that if I *do* lose any mothers it will not be because of my negligence.

In conclusion let me deviate from the scientific for a moment: A wayfaring man came upon three men working in a stone quarry. He said to the first one, "What are you doing?" The answer was, "I am cutting stone." He said to the second one, "What are you doing?" The answer was, "I am earning five dollars a day." He asked the third, "And what are you doing?" and this man answered, "I am building a cathedral." As true followers of Hippocrates we as practicing physicians are ever building "cathedrals" in all our work. But, we are especially building "cathedrals" when we save the lives of infants; and when we preserve the precious lives and the health of the mothers who are to care for these infants.

PAUPERIZATION OF THE PATIENT

A few alarmed observers never tire of shouting that there is a skeleton in the closets of hospitals and clinics. It is called, they aver, Pauperization of the Patient, and is responsible on the one hand for undermining the morale of the sick one, and on the other for using its bony fingers to keep dollars from the pockets of deserving doctors. A study recently published by the Chicago Institute of Medicine brings the fearsome creature out into the open. Trained investigators, guided by a committee of physicians and a committee on economic and social factors, including representatives of the University of Chicago, the School of Social Service Administration, Northwestern University, the Julius Rosenwald Fund, the United Charities and the Council of Social Agencies, gathered elaborate data concerning more than five hundred consecutive hospital and clinic patients in six large medical institutions of Chicago. After the facts of earnings, rent, unemployment, size of family, presence or absence of automobile and the like, were brought together and weighed, it was found that a little less than 4 per cent of these patients might have paid more than they did for their medical care, at least for a time. But on the other hand five times that number—or 20 per cent of the whole lot—had paid out more, in the opinion of the investigators, than they could afford. They had gone without food to buy medicine, or had sunk into debt in order to pay amounts completely disproportionate to their resources. More than half of the whole group of patients had employed private physicians previously for their illness, and had resorted to free or part-pay services only when their money was used up. To determine the ability of a family to pay for medical service, the authors conclude, is a complex matter in which consideration must be given to many factors, including income, living standards, expense of previous illnesses and probable expense and outcome of the present one. —Editorial, *The Survey*, Feb. 15, 1931.

RECURRING PREECLAMPTIC TOXEMIA: ITS CLINICAL SIGNIFICANCE*

Robert D. Mussey, M.D.
Rochester, Minnesota

PREECLAMPTIC toxemia occurs in approximately 3 per cent of pregnancies which are carried to the third trimester. In reporting the triple recurrence of eclampsia in the same patient, Laun, in 1928, reviewed the literature and stated that the percentage of recurrence of eclampsia is between 1.5 and 8 per cent. He expressed the belief that the higher rate is more nearly correct and quoted Bund who noted an increased incidence of recurrence of eclampsia in subsequent pregnancies. Schmechel reported 238 cases of eclampsia in 27,430 deliveries. Of these 238 patients, thirty-seven died primarily, two died during the course of the next year (cause of death unknown) and forty-one were not heard from. One hundred fifty-eight patients answered Schmechel's questionnaire. Eighty-three of these experienced subsequent pregnancies: thirty-five (42 per cent) without symptoms of eclampsia; thirty-three (40 per cent) with symptoms of eclampsia (five interruptions of pregnancy), and fifteen (18 per cent) with recurrent eclampsia. He quoted Zangmeister as stating that of forty-one patients with eclampsia who became pregnant later the eclampsia recurred in 12 per cent.

Gibberd reported fifty-one cases in which the patients were observed through at least two pregnancies at Guy's Hospital, the first pregnancy being associated with albuminuria. Four patients had chronic nephritis prior to the first pregnancy. The remaining forty-seven cases did not show evidence of nephritis early in the first pregnancy. In six of these cases in which the albuminuria was noted nine weeks (average time) prior to termination of pregnancy, chronic nephritis developed. In twenty-seven of the remaining forty-one cases in which recovery apparently was complete, the pregnancy terminated within three weeks of onset of albuminuria, and in fourteen cases later than three weeks afterward. In eleven (40 per cent) of the first group f cases and ten (70 per cent) of the second group, there was recurrence of toxemia in the second pregnancy. Gibberd expressed the belief that this indicates that residual injury is more common when the toxemia has been present for a longer period prior to delivery. He also quoted James Young who stated that in 31 per cent of cases of albuminuria of pregnancy the condition recurred. In a group of 225 patients with toxemia observed through two pregnancies, Kellogg noted that 80 per cent had recurrence of toxemia and elevated blood pressure.

The toxin causing preeclamptic toxemia produces more or less widespread arteriolar and capillary injury throughout the body, affecting chiefly the liver, kidneys, brain and heart. The liver, which appears to be almost invariably involved, has remarkable regenerative ability, so that patients recovering from the disease rarely, if ever, present symptoms of injury to the liver. The kidneys, which are perhaps less frequently and often less severely involved, may not recover so completely. In fact evidence indicates that a number of cases of chronic nephritis are a direct sequence of preeclamptic or eclamptic toxemia.

Caldwell and Lyle reported an incidence of 8 per cent of chronic nephritis after eclampsia. Gibson found that in five of fourteen cases of eclampsia and in two of twelve cases of preeclampsia chronic nephritis developed. Gibson quoted Koblanck as stating that 6.5 per cent of women had chronic nephritis as a result of toxemia of pregnancy. Harris, in a study of examinations of patients one year postpartum, found that three of twenty-seven patients with eclampsia and 60 per cent of patients with preeclampsia showed definite signs of chronic nephritis. Peckham observed that 12.2 per cent of primiparæ and 39.3 per cent of multiparæ had nephritis following preeclamptic toxemia. In his cases nephritis did not subsequently develop when the systolic blood pressure remained less than 170. When the systolic blood pressure was between 170 and 200, 15 per cent of the patients had nephritis, and when it was more than 200, 48 per cent had nephritis. Mussey, Keith and Rockwood reported fifty-seven cases in which chronic nephritis developed as a result of preeclamptic toxemia. After observing 225 patients with preeclamptic toxemia through two pregnancies sixty-eight of whom were observed through more than two pregnancies, Kellogg stated, "We have a general impression from this group that, on the whole, as progressive pregnancies occur, the patients tend to get worse earlier in pregnancy and that we are able to demonstrate with added pregnancies more and more established nephritic patients."

---

*From the Section on Obstetrics, The Mayo Clinic. Read before the Minnesota State Medical Association, Minneapolis, May 5, 1931.

Albuminuria, hypertension and edema are often apparent earlier in pregnancy in cases of chronic nephritis than in cases of preeclamptic toxemia, usually before the seventh month. The specific gravity of the urine is fixed or low and tests of renal function often disclose retention of nitrogen and phenolsulphonephthalein. Usually blood pressure is elevated and often there are changes in the ocular fundi resulting from previous acute nephritis. However, as Gibberd, and Kellogg have indicated, the injury to the kidney may be so slight that it is revealed only by the test of subsequent pregnancy.

I have observed ninety-seven patients with toxemia of the later months of pregnancy in a series of 2,906 deliveries, an incidence of 3.3 per cent. Ten patients had eclamptic convulsions, eighty had preeclamptic toxemia and seven had a history or evidence of nephritis prior to the first pregnancy. Thirty-five (36 per cent) of the ninety-seven patients were observed through at least one ensuing pregnancy; two of these patients had preëxisting chronic nephritis. One patient with eclampsia and thirteen with preeclampsia did not have toxemia in subsequent pregnancies. Nineteen (57 per cent) of the thirty-three patients with toxemia who had not had chronic nephritis experienced recurring toxemia in an ensuing pregnancy. Four of these, one of whom had eclamptic convulsions in the first pregnancy, had no evidence of persisting arterial or renal injury. Seven patients manifested suggestive but not conclusive evidence of chronic nephritis. Eight patients with recurring toxemia, none of whom gave a history or clinical or laboratory evidence of nephritis prior to the first pregnancy, showed definite evidence of a more or less severe grade of chronic nephritis, following one or more pregnancies in which there was preeclampsia; one of these patients had eclamptic convulsions in the second pregnancy. In one case of preeclamptic toxemia, in which the patient did not become pregnant again chronic nephritis developed.

None of the ten patients with eclampsia had prenatal care. Two became pregnant subsequently; one patient had recurring toxemia and one did not. Three patients died and two subsequently had chronic nephritis.

Of the ninety-seven patients with toxemia 26.8 per cent had more or less adequate prenatal care; 17.5 per cent had entirely inadequate care and 55 per cent had no care. Patients with recurring toxemia were about equally divided in the type of prenatal care.

Preeclamptic toxemia occurs during pregnancy as a primary disease of women without preëxisting evidence of disease of the liver or kidneys. During the course of preeclamptic toxemia many women manifest clinical evidence of acute renal injury. The types of injury may be grouped as follows:

(1) If the injury is slight, perhaps merely a circulatory disturbance, or slight degenerative changes, recovery may be complete; (2) if the injury is more severe it may become permanent, although so slight that it may not be detected by any test of renal function now available except the test of subsequent pregnancy, and (3) the injury may be sufficient to produce unquestioned chronic nephritis.

When patients who have had preeclamptic toxemia become pregnant again it will be observed that a large proportion (60 per cent in this report) will have symptoms of toxemia. Certain patients classified in group 1 will escape and others, although they may have completely recovered from the previous toxemia, will have recurrent toxemia as a result of the same unknown toxin which produced it the first time.

A larger proportion of patients in group 2 will be affected either by recurring toxemia or by symptoms arising from previously undetected chronic nephritis. Patients of groups 1 and 2 would probably fall in the group Stander has termed "low reserve kidney."

Most of the patients of group 3 will have symptoms, due in part to toxic factors and in part to the chronic nephritis caused by the previous toxemia.

Injury to blood vessels may occur even when there is no apparent renal injury. Following preeclamptic toxemia patients have been observed through several pregnancies with progressive arteriosclerosis and hypertension, but without demonstrable evidence of renal insufficiency.

COMMENT

A small proportion of pregnant women, possibly 3 or 4 per cent, have preeclamptic toxemia primarily. Evidence seems to indicate that a majority of the patients who have had preeclamptic toxemia will have similar symptoms in ensuing pregnancies. If this is so, it is evident that an attack of preeclamptic toxemia frequently causes some impairment of the patient's resistance to a subsequent attack, which may be due to: (1) lowering of physiologic defense; (2) sensitization of the tissues to certain foreign proteins, perhaps elaborated in the placenta or fetus or both, or (3) actual injury to tissues caused by the toxin. Little information is available concerning lowered physiologic protection or foreign protein sensitization following preeclamptic toxemia. Of the tissues or organs affected by this disease, the kidney is the organ which gives the most common clinical indication of the course and severity of the disease. When permanent injury follows an attack of preeclamptic toxemia the kidneys appear to bear the brunt of this injury.

SUMMARY AND CONCLUSIONS

Most patients who have had preeclamptic toxemia will have recurring toxemia if they become pregnant subsequently.

Recurring toxemia is probably due to the same factor or factors producing the original attack and affecting: (1) patients who have completely recovered from a previous attack; (2) patients with undetected residual renal or arterial injury subsequent to a previous attack, and (3) patients with definite chronic nephritis which existed before or developed subsequent to the previous preeclamptic toxemia.

In this series none of the patients with eclamptic convulsions had prenatal care and most of those with preeclamptic toxemia either had no care or the care was inadequate. In most instances a physician was not consulted until symptoms of toxemia were evident to the patient or relatives.

Adequate prenatal care for all pregnant women should lower the incidence of toxemia. Such care is possible only if the expectant mother consults her physician early in pregnancy and cooperates fully in carrying out his instructions.

The frequency of recurrence of preeclamptic toxemia and the relative frequency of residual chronic nephritis following this disease emphasizes the need for postnatal care and the importance of keeping certain patients under observation beyond the usual six or eight weeks, if need be, for six or more months after delivery. A woman who has had preeclamptic toxemia should not become pregnant again until a year or more has elapsed, and only after examination and estimation of the functional ability of the kidney to stand the strain of pregnancy.

ACCIDENTS OF LABOR*

James R. Manley, M.D.
Duluth, Minnesota

THE successful practice of obstetrics requires a reasonable knowledge of several different specialties. The pregnant woman may suffer from any disease during her nine months term. She could be classified as a medical case until labor sets in, as she may have to be treated for vomiting, thyroid disfunction, various infectious diseases, heart trouble and the different kidney and toxemic conditions found at this time.

At soon as the child is born she becomes primarily a surgical case and must be treated and handled according to the principles of surgery; she may suffer from surgical shock, hemorrhage, tissue injury and infection.

The subject, Accidents of Labor, which has been assigned to me is therefore a surgical subject and the treatment must be along surgical lines.

The accidents of labor include most of the complications which are sudden and dramatic in their onset, and which may result disastrously if proper treatment is not promptly administered, and which, indirectly, account for most of the maternal deaths.

Time is too limited to take up all of the accidents of labor in detail, and so this discussion will be limited to a few of the most common and important ones.

A laceration of the birth canal is the most common accident. Lacerations of the vaginal walls and perineum are mentioned in passing only to emphasize the necessity of careful aseptic surgical repair. This will militate strongly against infection as a virulent streptococcic infection may enter through lacerations.

RECTAL TEAR

A third degree laceration into the rectum, however, is a serious accident, and on its proper treatment depends the patient's future comfort and possibly her life. It must be repaired accurately and at once if the patient's condition will allow.

To make a good repair a nearly bloodless field must be obtained. If the placenta has separated and can be expressed, this should be done, a hypodermic of ergot given, and a large laparotomy sponge packed in the vagina to control seepage from above. Active bleeding points should be tied and the situation surveyed. If the placenta has not separated I give l.c. of pituitrin insert the pack as above alongside the cord and proceed with the repair while the placenta is undergoing separation. Someone must watch the uterus to detect accumulation of blood within its cavity. If active uterine bleeding occurs, the repair work is halted, the pack removed and another attempt made to express the placenta; if this fails and uterine bleeding persists a manual removal of the placenta is done, ergot given and the repair continued. Too much time must not be consumed as the patient may have a degree of shock from her delivery and a short anesthesia is desirable.

Mercurochrome is swabbed over the raw surface and two Allis forceps are placed at the edges of the rectal tear at the mucocutaneous border, the bowel straightened out by traction and the rent repaired by intestinal sutures of No. 0 chromic gut. Starting at the top a continuous suture is placed, endeavoring not to go through the mucous membrane of the rectum but only through the muscular coat. After this suture is tied at the lower end the next step is to secure the sphincter ani. Usually one end is protruding and the other end is retracted deep in its bed, because the rupture usually occurs in the lateral part of the muscle. The end of the muscle is secured by inserting an Allis forceps deep in the bed and pulling the muscle into view. It can be easily recognized because the fibers run transversely to the rectum. The severed ends are united with two or three interrupted No. 0 chromic sutures.

The next step is to bury the line of suture in the bowel by a continuous Lembert suture as is done in intestinal anastomosis. After this is done the tear in the vaginal floor is repaired with chromic No. 1 catgut and the perineal body reconstructed by wide sutures bringing the separated tissues together in the midline. The skin sutures are of silkworm extending widely to the sides into the perineal body and a silkworm gut suture is finally placed at the edge of the anus, which includes the united edges of the sphincter. This is placed under guidance of a finger in the rectum.

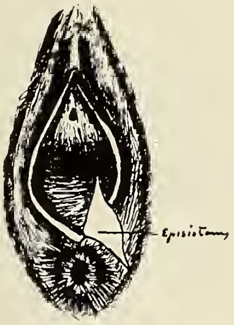

Fig. 1. Episiotomy.

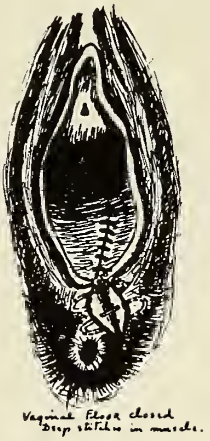

Fig. 2. Episiotomy repair.

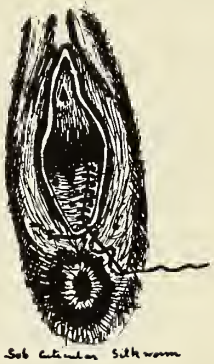

Fig. 3. Episiotomy repair.

The patient is kept on a liquid diet for four days and the bowels moved by magnesium citrate and a sweet oil enema on the fourth day.

The success of the repair depends on the degree of asepsis maintained. The presence of the opening into the rectum makes this difficult but careful attention to detail and the free use of mercurochrome make the effort well worth while and often perfect results are obtained.

LACERATIONS OF THE CERVIX

The question often is discussed as to whether the cervix should be examined and repaired at once.

In normal spontaneous labors and in low forceps deliveries it is not my practice to expose and repair the cervix. After difficult deliveries the cervix should be inspected, particularly if there is bleeding which may be coming from a cervical tear.

In home deliveries with insufficient help and poor light I would be inclined to let the cervix alone as long as there is no undue bleeding.

Cervical repair is not so very difficult if proper exposure and visualization can be obtained. The first and most important step is to have some one press down on the fundus, thus bringing the cervix to the vaginal outlet. The anterior and posterior lips are then grasped with sponge forceps and gentle traction made downward. By placing a retractor in the vagina on the side of the tear and pulling the cervix the opposite way a good exposure is made. A laparotomy sponge rolled into a compact cylinder and inserted into the cervix and lower uterine segment will tend to keep the blood from the uterus out of the operative field. The placenta may be either expressed first or not according to the amount of bleeding.

The first stitch of No. 1 chromic catgut is placed at the top of the tear. This will control most of the bleeding. Interrupted sutures are then placed about ⅜ to ½ inch apart. The cervix heals well and excellent results are obtained.

EPISIOTOMY

As a preventive measure against lacerations of the lower birth canal, excluding, of course, the cervix, there is nothing better in my opinion than an episiotomy. A central episiotomy for spontaneous labors after the perineum has become somewhat stretched and dilated by the descending head works very well. However if a central episiotomy is done before some stretching of the perineum has occurred the incision is liable to extend down to and often through the rectal sphincter.

In hard mid-forceps delivery a lateral episiotomy should be done, a deep incision being made before a tear occurs. This releases the pressure on all parts of the vaginal outlet and prevents tears and stretching of the tissues at the base of the bladder, injuries to the vaginal floor and tears in the rectum.

If the incision is accurately repaired a condition approaching a nulliparous outlet will be found two months after delivery. However, the scar will be tender for some weeks.

HEMATOMA VULVÆ

This is a rather rare condition. The lesion consists of a rupture of a vessel in the vulva and in one of my cases this was no external tear. The labor was spontaneous and nothing unusual was noticed at the time of delivery. About one hour later the interne phoned and said that the woman was in shock, with a weak thready pulse and clammy skin, and suffered severe pain in the vulva. He further reported that there was a large fleshy mass presenting at the vulva, which he said resembled the placenta a little which of course it was not. He said he had tried to remove it but couldn't. I went to the hospital and found a large hematoma one-half the size of a child's head with no sign of external tear. The patient was anesthetized, the hematoma opened, the blood removed and a bleeding vein found and tied. The patient was given some glucose intravenously and recovered rapidly.

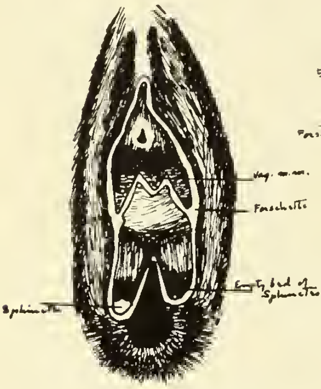

Fig. 4. Third degree laceration.

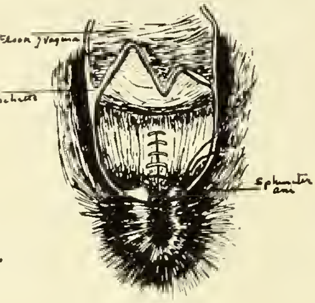

Fig. 5. Repair third degree laceration.

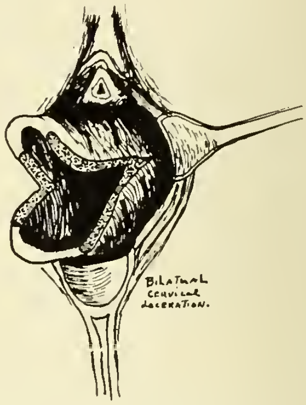

Fig. 6. Laceration of cervix.

ABRUPTIO PLACENTÆ

This serious condition is often associated with toxemia. The next most common cause is torsion of the uterus (Polak) with blocking of venous return. Polak says that taking the knee chest position three times daily during pregnancy has diminished the frequency of this condition, in his clinic. Direct trauma may also be a factor.

Symptoms consist of a sudden severe adbominal pain, usually with some vaginal bleeding. External bleeding is often a later sign. The pain is constant and the uterus becomes boardlike. Some shock is always present. In severe cases no fetal heart is heard. The symptoms may appear before true labor starts or in the early part of labor.

Treatment may be conservative or radical.

If the patient is a primipara with an undilated cervix and labor has not begun, my personal preference is for cesarean section. The uterus may be sutured and left if it contracts well and there is no bleeding, and if there has been no vaginal manipulation. Otherwise a hysterectomy should be done. Blood transfusion is very important and should be carried out if possible, otherwise glucose or acacia should be given intravenously.

Conservative treatment consists of morphine for shock, preparations for delivery, and rupturing the membranes. The cervix and vagina are packed with mercurochrome gauze and a tight abdominal binder applied. Three minim doses of pituitrin are given every twenty to thirty minutes. The blood pressure and hemoglobin are watched every half hour and a blood transfusion given. If labor is progressing all may be well. Delivery should be effected as soon as possible. After delivery the placenta is expressed or manually removed and it is usually wise to pack the uterus with mercurochrome gauze at once.

If however, under the conservative treatment, labor does not progress, the blood pressure and hemoglobin become quite low, and the general picture changes for the worse, section must be done. As there has now been considerable vaginal manipulation a hysterectomy must also be done. However, if conditions forbid operative treatment, good results often follow the more conservative method of treatment.

RUPTURED UTERUS

The uterus may rupture as a result of violent ontractions in the presence of an obstacle preventing advance of the head or it may be ruptured y the efforts of the attending physician to deiver the baby.

After rupture has occurred, the only recourse is laparotomy preceded or followed by blood transfusion or glucose intravenously. If there has been no vaginal manipulation, it may be wise to remove baby and placenta and repair the rent, or it may be necessary to remove the uterus, depending on the location of the rupture and possibility of infection.

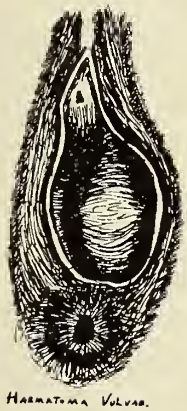

Fig. 7. Hematoma vulvæ.

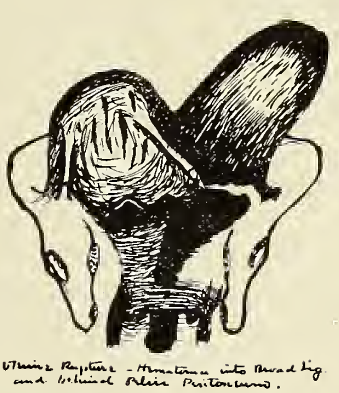

Uterine Rupture - Hematoma into Broad Lig. and Internal Pelvic Peritoneum.

Fig. 8. Rupture of uterus during version.

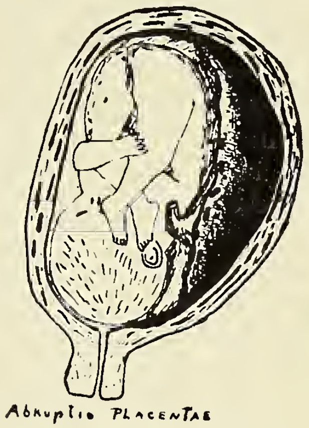

Fig. 9. Abruptio placentæ.

The first type, as a result of violent contracons, often following the administration of ituitrin, is usually preceeded by tetanic contracons and often a Bandls contraction ring is resent. If the uterus completely relaxes between ains, even if they are very strong, there is not uch danger of a rupture. This type probably oes not occur all at once and at the first slight earing the uterus becomes irritable and becomes tanically contracted. The succeeding hard conactions occurring on top of the tetanic contracon completes the rupture. This type usually uptures through the body of uterus into the eneral peritoneal cavity. After complete rupture ccurs the contractions cease, the presenting part, not fixed in the pelvis, recedes and the patient anifests the usual signs of shock. The conacted uterus may be felt alongside the fetus in e abdominal cavity.

In the presence of symptoms suggesting the mminence of rupture, the uterus should be ven a rest by a dose of morphine or if the mptoms are very marked and the morphine es not have the desired result, the patient ould be anesthesized and preparations made r instrumental delivery, embryotomy or sarean section. Version should not be attempted der these conditions.

The other type occurring during the course of operative delivery generally occurs during a version or it may occur during a forceps delivery through a poorly dilated cervix, the cervical tear extending up into the lower uterine segment.

The greatest safeguard against rupture of the uterus during a version is a perfectly relaxed uterus, if the bag of water has long been ruptured and the uterus is tetanically contracted or a contraction ring is present, version is difficult and very dangerous. Deep anesthesia is essential, either by chloroform or ether. Ethylene is not sufficient to relax the uterus and all manipulations must cease during the slight contractions which occur even during anesthesia.

A rupture of this type is usually in the lower segment and often into the broad ligament as in the illustration. There is generally profuse hemorrhage, the uterus contracts poorly and the patient at the conculsion of the delivery is in shock. With these symptoms the interior of uterus should be explored at once to rule out rupture.

In one case seen, the attending physician gave a history of delivery by version of a live baby, profuse hemorrhage and considerable shock. The patient was in poor condition all the time following delivery and nearly every day a rather brisk bleeding occurred. Several blood transfusions were given. When I saw her six days later there was a hard mass in the left lower abdomen separate from the uterine body, extending high up toward the kidney region and the patient was in bad shape. A diagnosis of rupture into the broad ligament behind the peritoneum was made. She did not seem to be in a condition to withstand a laparotomy and so she was anesthesized and the uterus explored with the findings as illustrated. A large blood clot was removed and the cavity packed; it was impossible to identify any bleeding artery although it was surmised that the uterine artery had been torn. However, the packing failed to check the bleeding and the patient died eight days after delivery.

An autopsy was obtained with the findings as illustrated. Note that the cervix itself was not torn. At autopsy it was very difficult to identify the torn uterine artery, so great was the infiltration with blood. This supported our opinion that laparotomy was not advisable as the operation would have been long and difficult.

In conclusion I only want to emphasize the fact that the results you will obtain in treating the accidents of pregnancy will depend on your previous conduct of the case. If labor has been conducted in an aseptic manner with no vaginal examinations and your patient has not been infected, the results will be fairly satisfactory. If on the other hand there has been much manipulation and the patient has been infected the accidents of labor will result disastrously.

DISCUSSION OF PAPERS BY DRS. BERGHEIM, MUSSEY AND MANLEY

Dr. J. C. Litzenberg (Minneapolis): This is one of the proudest moments of my life for the reason that the exhibit this morning is a testimony that in Minnesota conservative obstetrics is practiced. You have learned from this symposium this morning one of the reasons why the maternal mortality in Minnesota is lower than in any state in the Union.

You have heard specialists discuss various phases of the subject, and you have also heard a country doctor read a paper which is worthy of any specialist and which shows why our maternal mortality is being reduced in Minnesota until it is now the lowest because maternal mortality is not reduced by specialists but by the general practitioner.

The work of Dr. Berkwitz is of special significance in the question of what occurs in the early toxemias of pregnancy. There has been too much emphasis placed upon the toxic character of the vomiting of pregnancy. Much of the early vomiting of pregnancy is due to neurosis and should be treated as such. However, if we cling to this idea too tenaciously with a one-track mind, just because a majority of the cases are not toxic, we are liable to fall into error as Dr. Berkwitz's paper has proven.

It is unfortunate that so many of the patients that Dr. Berkwitz has reported, died. One of them died under my hands on the table because we did not see her early enough to recognize the toxic nature of her condition and to empty the uterus. The lesson in this is that when patients do not respond to the usual treatment for vomiting of pregnancy, they must be assumed to be toxic and the uterus emptied in time to save the patient. Of course, a good many of them come into our clinic in rather a severe condition. But I think the lesson of this is that the vomiting of pregnancy, the early vomiting of pregnancy, may be toxic, and the patient may lose her life. These patients, if they do not respond to the ordinary treatment, should be promptly aborted.

One of the reasons I feel so proud of this program this morning is that it is a prophylactic program. Every one of the speakers has emphasized the necessity of prophylaxis, and they are bringing into the picture the necessary emphasis which should be placed upon postpartum as well as antepartum care. In other words, they have emphasized, particularly Dr. Mussey, Dr. Bergheim and Dr. Barry, the necessity of following these women in after-care, not only until a woman is delivered of a healthy, living baby, but that woman must be followed until she is restored to perfect health.

Dr. Barry has emphasized the postpartum care, because of the consequences, immediate and remote, of puerperal infections.

When we realize that we have endocarditis, peritonitis, abscess of the lung, nephritis, following the toxemias of pregnancy and following the infections of delivery, we may then lay emphasis on the postpartum care, which means that the woman should be watched until she is restored to perfect health.

Dr. Manley emphasized the necessity of prophylaxis in the accidents of labor, because many of these accidents can be prevented. I was glad to note that he took such a sane position. That word "sane" is a favorite of mine, because I don't exactly like the word "conservative" because one is apt to think that the conservative is the man who does nothing.

I think the late Dr. J. E. Moore described a conservative in the best words that I have ever heard when he said: "A conservative is the man who knows when and how to be radical."

These men you have listened to this morning are possessed of skill to do any of the radical procedures of obstetrics, but their sanity keeps their feet on the ground.

I was particularly pleased with the figures that Dr. Mussey presented, because you know that we have been going through two particular things in regard to the toxemias of pregnancy which have considerably disturbed us.

About twelve years ago from Williams' Clinic came a paper which said that the women who have had eclampsia or toxemia are no more liable to have subsequent attacks (and the figures even showed a lesser liability) than the women who have not had it. We have also been going through a discussion among the pathologists. "Is the condition of the kidney with which we deal in the toxemia of pregnancy, a nephrosis or a nephritis?" We have been deceived by the large number of women who apparently completely recover from their toxemias of pregnancy.

In the marvelous symposium on the kidney, which was held at the University last summer by men from all over the world who had made special studies of the kidney, the idea of nephrosis was very vigorously combated. If those who advocate the idea of the nephrosis are compelled to surrender to the idea that this thing with which we deal, as far as the kidney is concerned in the toxemia of pregnancy, is a nephritis, then Dr. Mussey has the explanation of the figures which he presented. They are rather striking.

Let me say just one word about so-called recurrence. I doubt if this is a true recurrence of a preeclampsia. I think it is symptomatic recurrence because the kidney is damaged. I have had a theory. You know, a theory is something which you figure out more or less from a philosophical standpoint, but data for which does not exist for its absolute proof. My theory has been this, that whether a woman has trouble in a future pregnancy, when she has had a previous toxemia, depends upon the amount of damage done to her kidneys during her toxemia. I believe this is logical. I admit it is only a theory, but Dr. Mussey brought a very great deal of proof of it in his paper this morning.

Dr. Mussey emphasized the necessity of prophylactic care for these women. I know of nothing in the practice of obstetrics that needs postpartum care more than to follow every woman who has had a toxemia, by observation and treatment until she has returned to absolutely normal health; in other words, until the albumin has all disappeared, until her high blood pressure has disappeared, but that is not all—until we know that her kidneys are functioning properly. Even then we cannot be assured that she will not have a recurrence later on, because if my theory be true that whether she has subsequent atacks or not depends upon the amount of damage done to that kidney, even then she may have recurrence, because we all know that the human kidney is four or five or maybe more times greater in functional tissue than is necessary to preserve life. Therefore, a kidney may be considerably damaged so that the woman may go on to good health and live out her life expectancy if an additional burden be not thrown upon those kidneys, which is done by a subsequent pregnancy. Therefore, when this subsequent pregnancy throws that extra burden upon the kidney, the damaged, although apparently healthy, kidney is found to be insufficient.

I have left the discussion of Dr. Bergheim's paper to the last for the reason that he is the one who exemplifies the general practitioner in Minnesota. There are men like him all over this state who are practicing sane obstetrics. We specialists in the Twin Cities who are so proud of our practices do not have more patients in obstetrics than Dr. Bergheim has out in a village of 1,000 people. He is practicing that thing in the country which we as teachers have preached for years. When we talk about this prenatal care and this care during labor which Dr. Barry emphasized, and the postnatal care which particularly Dr. Mussey has emphasized, many country practitioners say: "You don't know anything about it. You are nothing but a city guy and a teacher." You won't listen to me; I don't blame you much. Nevertheless my early practice was in a labor Ward of Minneapolis. If there is anything worse in the country than the things I met in city practice, when I had to sleep on the fuzzy side of a rug and often on the soft side of a pine board during the night, I should like to know it. Nevertheless, I admit I am from the city and I am only a teacher. But Dr. Bergheim and men of his type all over this state are practicing sane, complete obstetrics in the country and I believe that is the reason that the maternal mortality in Minnesota is lower than any state in the Union.

ALLERGY AND PNEUMOCOCCUS LOBAR PNEUMONIA*

H. A. Reimann, M.D.
Minneapolis

THE discovery of anaphylaxis and its relation to protein intoxication has been followed by numerous efforts to draw an analogy between this phenomenon and the manifestation of certain acute infectious diseases. At present it appears that allergy or hypersensitiveness to bacterial protein plays an important rôle in tuberculosis, syphilis, acute rheumatic fever, and probably in acute nephritis. The suggestion that lobar pneumonia as a disease represents a form of allergic or anaphylactic reaction was made by Friedberger and by Rosenow in 1911. Certain features of lobar pneumonia, such as the sudden onset with chill and fever and the sudden drop of the fever, resemble the reaction which often follows the injection of foreign protein in an experimentally sensitized animal. Numerous attempts have already been made to demonstrate the presence of allergy in humans and in experimental animals by employing skin tests, using the pneumococcus or its products as antigen. Varying degrees of success have been attained.

Interest in the subject of the allergic nature of lobar pneumonia has been recently renewed, chiefly through a series of publications by Lauche[1, 2, 3] and by the decisive experiments of Avery and his associates[4, 5] concerning specific anaphylaxis with the pneumococcus and its products. Lauche approaches the subject by comparing the difference in the reaction of young infants as compared with adults to pneumococcus infection. He points out that infants less than four months of age seldom contract pneumococcus lobar pneumonia, and that when infection does occur, it is mild. The explanation for the difference in response in infants and adults assumes that infants have not as yet had the opportunity to become sensitized to the pneumococcus, and thus do not react in a violent, anaphylactic manner when exposed to an infecting dose of pneumococci. With increasing age, opportunities for contact with the pneumococcus increase in proportion. Numerous mild infections, for example, sinusitis, mastoiditis or conjunctivitis, may occur in early childhood and later, which eventually induce a state of hypersensitiveness reaching its height in adult life, at a time when lobar pneumonia is most common and most severe. It is Lauche's contention that pneumococci invade the lung tissue of a sensitized individual near the hilum or the adjacent lymph nodes, where the first inflammation and bacterial growth occur. The inflammatory reaction at the hilum obstructs the lymphatic drainage of the lobe and induces a back flow of lymph toward the periphery. By this reversal of lymph current, favored by the sparseness of valves in the lymph channels, pneumococci or their products (antigen) are distributed throughout the lobe. The distribution of antigen throughout the lobe can probably also be accomplished by the normal ebb and flow current of the pulmonary lymph stream. When the concentration of antigen in the sensitized lung attains the stimulation threshold (Schwellenwert), the explosive anaphylactic reaction manifested by the sudden chill, fever and outpouring of exudate occurs. The height of the threshold depends upon the degree of sensitivity. Lauche's theory is attractive and has considerable experimental data to support it.

Soon after Friedberger suggested the allergic nature of pneumonia, both he and Schittenhelm[6] succeeded in producing sterile anaphylactic pneumonia in sensitized guinea pigs by the introduction of the shocking dose of protein into the lungs. Ishioka's histologic studies[7] demonstrated that in many instances the histologic picture of the pneumonia produced in this manner closely resembled that of a lobar pneumonia in humans.

As early as 1904, before allergy was considered, Wadsworth,[8] in endeavoring to induce pneumonia in rabbits by intratracheal injection of pneumomoccus cultures, noted that inflammatory localization in the lung occurred only in those animals which had previously been immunized. Otherwise the rabbits would either remain well or would promptly die from pneumococcus septicemia. Twenty years later, Stillman and Branch[9] noted the same requirement necessary to produce pulmonary localization of pneumococcus infection in experimentally infected mice, namely, that pulmonary inflammation occurred only in mice which had previously been partially immunized. Normal unimmunized mice promptly died from an overwhelming generalized infection. Although Wadsworth, and Stillman and Branch considered partial immunity as one of the chief factors determining the pulmonary localization of infection, it appears now that the state of hypersensitivity must also be considered.

---

*From the Medical Service, University Hospital, Minneapolis.

Sharp and Blake[10] have recently reported experiments similar in nature to those of Friedberger, Schittenhelm and Ishioka. They have found that pneumococcus autolysates elicit an acute exudative inflammatory response when injected intratracheally into the lungs of specifically sensitized rabbits. Similar intratracheal injections in normal (non-sensitized) rabbits failed to incite any pulmonary reaction. In other words, the inflammatory reaction in the lungs in response to the contact with pneumococcus autolysate depends upon the specific allergic state of the animal. It was also found that a fairly close parallelism exists between cutaneous and pulmonary hypersensitiveness to pneumococcus autolysates in the rabbit.

Important observations have also been made concerning the relation between immunity and pneumococcus infections in humans. Clough,[11] and Robertson and Cornwell[12] have shown that many normal individuals possess demonstrable immune bodies in their blood. Furthermore, Robertson, Terrel, Graeser and Cornwell[13] have shown that individuals with demonstrable specific immune bodies in their blood serum may contract lobar pneumonia. They explain this apparently paradoxical fact by assuming that local changes take place in the lung, of such a nature as to provide conditions for the growth of pneumococci, while at the same time protecting them from the bactericidal action of the immune bodies in the blood. However, another explanation is possible, as the latter investigators also suggest, namely, that allergy may play a rôle. The demonstrable antibodies were probably provoked by previous mild pneumococcus infections, and it is possible that these patients are both partially immune, and hypersensitive as well.

Avery and Tillett[4] have shown that anaphylactic shock can be induced by the injection of small amounts of type-specific carbohydrate derived from pneumococci in guinea pigs passively sensitized with homologous antipneumococcus rabbit serum. Tillett and Francis[5] and Kramár and Gyüre[14] have shown that specific skin reactions characterized by urticaria-like wheals, may be obtained in pneumonia patients after the crisis at the site of an intradermal injection of pneumococcus carbohydrate. The cutaneous response when obtained was always elicited by the carbohydrate homologous to the type of pneumococcus which caused the infection. The skin sensitivity was found to parallel the presence of circulating type-specific antibodies. The presence of sensitivity was, however, independent of the presence of type-specific antibodies; in other words, immunity and hypersensitivity are not identical. The independence of pneumococcus immunity and allergy has been further demonstrated by Rich and Brown.[15]

Comment: There are at present, therefore, a number of facts and theories in regard to the allergic nature of lobar pneumonia:

1. Anaphylactic pneumonia has been produced experimentally.

2. It is usually necessary to use animals which have previously been exposed to pneumococci before pneumococcus lobar pneumonia can be produced experimentally.

3. Specific skin hypersensitiveness is demonstrable in patients after an attack of lobar pneumonia.

4. Individuals with circulating specific immune bodies may develop lobar pneumonia.

5. The theoretical consideration of Lauche explains the mildness of lobar pneumonia in young infants on the basis of a lack of hypersensitiveness.

Although a number of factors seem to indicate the importance of hypersensitivity in lobar pneumonia, others suggest that hypersensitivity is not alone responsible for the characteristic reaction. Lobar pneumonia may on rare occasions occur in very young infants, who, according to Lauche, are not yet sensitized. Under these circumstances the pneumonia often runs a mild course and probably involves factors of immunity only. Non-immune infants, like highly susceptible experimental animals, often die from an overwhelming septicemia without pulmonary localization. In many adults lobar pneumonia commences rather insidiously, without manifestations of the prompt allergic reaction characteristic of hypersensitivity. It is possible, however, that these atypical manifestations may only indicate the varying intensity of the two factors of immunity and hypersensitivity, and that under certain circumstances one or the other may condition the response. Hypersensitiveness does not appear to play any rôle whatever in the production of experimental pneumonia in monkeys (Blake and Cecil[16]) or in dogs (Terrell and Robertson[17]).

There are obviously many facts to be discovered before the exact relationship of hypersensitivity to pneumonia is established, but there are many indications that the allergic state may, at least, have some influence and may modify the response to infection to some extent. The question arises as to the subtle equilibrium which apparently exists between immunity, hypersensitiveness and infection. What part do the commonly recognized predisposing factors play? Do they diminish immunity and permit the invasion and growth of pneumococcus and subsequent contact of these organisms or their products with a hypersensitive lung? Is immunity decreased or is hypersensitiveness increased, or are both factors involved? Does the supposed predisposition of one attack of pneumonia to subsequent attacks depend upon a continual hypersensitive state or are individuals who have repeated attacks of lobar pneumonia unusually hypersensitive or unusually non-immune?

SUMMARY

A recent theory regarding the pathogenesis of lobar pneumonia as advanced by Lauche, regards allergy or hypersensitiveness to pneumococcus as an important factor. The mechanism of infection operates as follows: pneumococci invade the lung tissue or the bronchial lymph nodes of a sensitized individual. The first inflammation occurs near the hilum, from whence pneumococci or their products (antigen) are distributed throughout the lobe which drains into the area, by means of the reversal of the lymph stream. When the concentration of antigen attains the stimulation threshold, the sudden inflammatory exudative reaction of lobar pneumonia occurs.

Other experimental data published by numerous investigators further suggest that pneumococcus lobar pneumonia is conditioned in part, at least, by a state of allergy or hypersensitiveness of the individual to the pneumococcus.

VINCENT'S DISEASE*

Robert I. Rizer, M.D.
Minneapolis

By VINCENT'S DISEASE I mean an infection caused by the fusio spirochetal organism of Vincent. It is usually located in the mouth, but it may be found in any part of the body. The disease may be acute or chronic; it is infectious, and it may cause death.

At the present time Vincent's infection is of greater interest than ever before because the disease is decidedly on the increase and has been since the Great War.

We may well ask, what is the reason for such an increase? Is it not a fact that besides the congestion and the increase in the prevalence of the general infections, there must be carriers, people chronically infected who are not recognized as such and who are disseminating the disease?

Mucous membrane contact with infected material, usually saliva, is the common method by which the disease is contracted. Coughing, unclean dishes, cigarettes, pipes, dental instruments, as well as kissing, may be factors.

In 160 individuals Miller found the organism in 77 per cent; Brams discovered its presence in the crypts of 82 per cent of 100 pairs of tonsils. It has not been present in the mouths of edentulous people, and we have rarely found it in what we have termed normal mouths. It is probably an opportunist acting in a secondary role—more saprophitic until some conditions arise which lower the resistance of the local tissues, such as: erupting third molar teeth, pyorrhea, receding gums, pre-existing pockets, cavities that are not easily accessible to the tooth brush, faulty dentistry, unclean mouths, tobacco, mercurial stomatitis, also the associated diseases such as adenoids, diphtheria, measles, syphilis, scarlet fever, purpura, sepsis, diabetes, tuberculosis, malnutrition, scurvy, and malignant growths; then the organism may grow and become the dominant cause of the pathological condition.

To quote from Tunnicliff: "The fusiform bacilli and the spirilla with which they are always associated are different forms in the life cycle of one organism.

"The organism is an obligate anerobe; it grows at 36 degrees C. but not at room temperature. A slightly offensive odor is given off in successful cultures. The bacilli are non-motile and insoluble in 10 per cent saponin or bile.

"Cultures were made anerobic according to Wright's method, by saturating the cotton stopper with a 5 per cent solution of sodium hydroxide, a piece of pyrogallic acid the size of a pea having been placed on the plug; the tube was closed with a cork and sealed with paraffin.

"The colonies on blood agar are whitish with a slightly violet tinge, smooth and moist, edges regular, from 1 to 3 mm. in diameter. In ascites agar shake cultures, the colonies are lenticular with even borders, and are slightly brownish. When well separated, they may become larger. A puff-ball appearance of the colonies has not been observed.

"The organisms grow well on Loeffler's blood serum, autoclaved rabbit brain, 1 per cent dextrose broth, distilled water and ascitic fluid 1:3, plain and dextrose broth with ascitic fluid 3:1, plain and dextrose agar to which blood or ascites fluid has been added in the proportion of 3:1. It requires some body fluid for growth, but enough may be carried over on inoculation for one generation. In dextrose broth the growth is diffuse at first, later settling into clumps; in other fluid mediums it is flocculent. Cultures were also successful on blood agar and in ascites broth, to which were added solutions of either 5 drops of 20 per cent sodium chloride solution, 1-2 drops of 10 per cent sodium hydroxide or 1-2 drops of 10 per cent acetic acid to each 5 c.c. of medium. Larger amounts of these substances generally inhibited growth. The addition of fresh rabbit kidney tissue did not appear to enhance the growth. The hydrogen-ion concentration of the medium was 7.4 to 7.6.

"The bacillus ferments lactose, dextrose, salicin and inulin, but not mannite, maltose, or sacchrose."

Veillon, Zuber, Weaver, and Tunnicliff on injecting pure cultures subcutaneously into animals produced local abscesses. Smith injecting sputum into the groin of guinea pigs produced local abscesses at the point of injection, and metastatic abscesses in the liver, spleen, and lungs. The same combination of organisms was present in the metastatic abscesses as in the original sputum. By inoculation into the groin of other animals the disease was transmitted from guinea pig to guinea pig at ten day intervals for five passages. Pus from one of these pigs was inoculated in 0.25 c.c. amounts into the tracheas of four rabbits; two died of pulmonary gangrene and two of pulmonary abscesses associated with empyema.

---

*Read before the Minnesota Society of Internal Medicine, Minneapolis, April 13, 1931.

The bacilli appear as pointed, straight, or curved rods 2-10u in length. The spirilla appear as straight or curved forms with 2-8 curves and from 3-10u in length. They stain well with gentian violet and carbo-gentian violet. We have used the gentian violet in our work. A platinum needle is applied to the suspected areas; the material obtained is spread on a clean glass slide, dried, and fixed in heat; the stain is then applied, washed, dried, and examined under an oil emersion lens.

On routine examinations we have been finding for some time patients with the soft parts about some teeth swollen; the margins have been very red and have been slightly separated from the teeth. These parts might be covered in part or whole by a greyish exudate; ulceration has usually not been present, the breath has had an unpleasant odor, and in the mild cases there have been no constitutional symptoms. These people were sent to their dentist for care. In some cases a diagnosis of gingivitis or pyorrhea was made; mild treatment was given. We were surprised to see that these people did not improve.

What was this condition? Was it a local infection in the mouth, a local manifestation of a general infection, a deficiency disease, or a general blood disease? The routine physical examination had been made and the laboratory examinations which included: complete blood, blood metabolites plus calcium, platelets, bleeding and clotting time, Wassermann and Kahn, urine, and gastric secretions. X-rays of the teeth were made. We then added to our routine the examination of smears made of the material obtained from the suspected teeth. In our first 100 cases which presented the above picture we found that 98 per cent showed large numbers of the Vincent organisms. Since that time we have found 100 per cent positive smears.

The patients are sent to their dentist with a diagnosis of chronic Vincent's infection and a combined treatment is administered. We are now getting results.

Coöperating with the dentist, the doctor should see that the patient is in the best possible physical condition. A liberal general diet should be given avoiding condiments, pickles, and highly seasoned and coarsely divided food. Smoking, and the use of tooth picks and dental floss should be avoided. The dishes and towels should be isolated. The patient should be instructed to cover his mouth whenever he coughs or expectorates. Any sputum should be burned.

The dentist, on his part, should employ a regime of mild instrumentation and cleaning the tissues, avoiding any trauma and procedure that might lower the resistance of the soft parts which would make a nidus for any organism. In addition we like to use a mouth wash composed of equal parts of alcohol, peroxide and glycerine, which may be used as a spray about the teeth. A thick perborate paste may be used locally. Cleaning the teeth with a soapy tooth paste aids in removing the organism. Should there be extensive infiltration or involvement, a local application of a 10 per cent solution of salvarsan may be applied.

It will require several days before the soft parts will have a healthy appearance. It is at this time that corrective dentistry should be started. This is most important as the future condition of the patient's mouth rests upon the treatment by the dentist, i.e., cleaning the mouth and teeth, and correcting any abnormal condition. This will insure the patient against recurrence once a cure is effected.

In any mouth in which Vincent's infection is present, it is dangerous to extract teeth or perform any surgical operation about any part of the body until the infection is controlled or cured.

The case of one man is instructive. He had had an infected mouth which had been treated in the East. Upon his return to Minneapolis, a chronic recurrent appendix became acute; his mouth seemed to be clear but no smear was made at this time. The appendix was removed; his condition following the operation remained normal for two days, when following a slight chill his right and then his left parotid glands swelled. The swelling increased so that his face appeared to be round; his temperature was 104°; he was delirious; one of his finger joints was swollen and painful; a thick yellowish-green material could be expressed from Steno's ducts. The cultures and smears were said to contain only the usual pus producing organisms. The patient died.

Within a short time another man came to see us because of a swollen jaw. We found him with a high fever and his right parotid gland was badly swollen. The soft parts about the upper and lower teeth on the right side appeared as described above. The smears made from the material from Steno's ducts were examined immediately and were found to contain large numbers of Vincent's organisms. A diagnosis of Vincent's infection was made and four days later, following proper local and general care, the man left the hospital with no symptoms and the gland nearly resolved.

Another case is that of a man who had been sick two days, delirious, with a high temperature. He had a facial erysipelas involving the nose, cheeks, forehead, eyes, ears, and neck. The mucous membrane about the teeth was very red and covered in some areas by an exudate; his breath was foul. Smears showed the presence of large numbers of Vincent's organisms. He was taken to the hospital, the erysipelas was treated by X-ray, neo salvarsan was given to him intravenously and was used locally in his mouth. His dentist coöperated in the treatment, and the patient made a splendid recovery.

The sinuses and bones of the head are frequently infected by Vincent's organisms, and from these areas nearly every part of the body may be infected. Osteomyelitis, meningitis, brain abscesses, chronic otitis, media abscesses and gangrene of the lungs, pericarditis, ulcers of the stomach or rectum, abscesses in the glands or any viscera may be caused by Vincent's organism. In fingers infected from biting the nails, and in the intrauterine secretions following abortions, Vincent's organisms have been found.

In the acute Vincent's infections there is an abrupt onset with chills, fever, weakness, general aching, and local symptoms such as burning, pain, salivation, dysphasia, tender teeth and swollen submaxillary glands. The red swollen soft parts about some or all of the teeth will be seen with the red infiltration extending locally or generally through the mouth into the pharynx, covered by an exudate and a local or generalized ulceration. A diagnosis is easily made in the chronic form. The appearance, with the positive smears and culture, identify Vincent's disease.

The infection should be recognized and proper treatment instituted early before destruction of the tissues occurs. In this case the prognosis is excellent and the treatment of the disease is short. Where tissue destruction is present, the infection is difficult to manage and the treatment will be prolonged.

If the dentist and physician coöperate in recognizing and treating Vincent's disease, great headway will be attained in the stamping out of this disease which is becoming more and more prevalent.

THE FOUNDING OF THE RAMSEY COUNTY MEDICAL SOCIETY*

John M. Armstrong, M.D.

Saint Paul

SIXTY-ONE YEARS ago this month the Ramsey County Medical Society was born. The minutes of the first meeting and in fact the minutes of every meeting since, are intact and in our possession. Those physicians in actual attendance at the initial meeting were as follows: D. W. Hand, A. Wharton, Wm. Banks, C. W. Boardman, S. D. Flagg, E. H. Smith, John B. Phillips, Wm. Ray, Samuel Willey, Frank Lawson, and Adelard Guernon. In addition to these the following were admitted as charter members: Thomas R. Potts, David Day, A. G. Brisbine, J. H. Stewart, Franklin R. Smith, John Steele, J. H. Murphy, Brewer Mattocks, Chas. E. Smith, Martin Hagan, and William Baldwin.

Their portraits may be seen grouped together on our Library walls. Unfortunately these portraits were collected many years after the event of our founding, and in most cases portray these men much older than they were in 1870. You will note on reading the minutes of the first meeting that the Society considered itself a reorganization of the St. Paul Academy of Medicine and Surgery.

In 1901 when Dr. Boeckmann read a history of our society as his retiring presidential address, he was able only to state that in our library was a minute book of this older organization of physicians with the minutes torn out. All that was known about the Academy was the names of the members which were written on the inside of the front cover. Dr. Boeckmann expressed the hope that at some future date the missing pages might be found, a hope not yet fulfilled.

Nevertheless research has given us much information about the Academy. It was organized March 1, 1860, its membership consisting of twelve men as follows: T. R. Potts (Pres.), A. G. Brisbine (V. P.), A. Wharton (Sec), John Steele (Treas.), Samuel Willey, J. H. Stewart, F. R. Smith, J. A. Vervais, Wm. H. Morton, E. Braun, Francis Reiger, and D. W. Hand; practically the same who were the majority of the founders of our society. We have accomplished much in the past sixty years, but the older society also accomplished a great deal in the six years of its activity, and no doubt the ideal for which the older society strove was the ideal kept in view when our present society was established, though we have been slower in our progress.

To those of you who think our present dues too high, I might mention the fact that the dues of the Academy were twenty-five dollars a year, and none of it was paid to the State Association, which did not then exist. The Academy maintained "two gas lighted rooms on Third Street, above George Benz Beer Saloon," had a chemical laboratory, an electrical machine for physiological experiments, and owned a compound microscope of the best make obtainable at that time. It is stated that when the scientific meeting adjourned a social meeting often continued downstairs.

The Chicago Medical Journal for June, 1861, in an editorial about the Academy, states, among things highly complimentary, that at the end of the year the receipts were $620.72, expenditures $462.93, and a cash balance to date of $367.07. You may wonder where all this money came from. On April 15, 1860, we find that the newly formed Academy petitioned the City Council of St. Paul, in a letter signed by Doctors Potts, Brisbine, and Wharton, that their president, Dr. Thomas R. Potts, be appointed city physician. The council thereupon elected Dr. Potts city physician for one year. The emolument of this office was five hundred dollars per year. The twelve members of the Academy then took turns of a month each, acting as city physician, and turned in the salary to the Academy. It is needless to say perhaps that the war between the states was the cause of the demise of the Academy. Of its twelve original members, nine served their country in the army during the years 1861-1865.

When the conflict was over, Morton was dead.

---

*Read before the Ramsey County Medical Society, St. Paul, February 27, 1931.

Braun had gone to Little Falls and Vervais had dropped out, and Rieger was leaving St. Paul. Thus but seven of the original members remained, though Doctor Mattocks was admitted to membership in 1865. The remaining members, feeling that they alone could not carry on, and being unable to determine the ethical and professional status of the new members of the profession who flocked into St. Paul after the war, were placed in a quandary. In addition, their articles of incorporation made them rather a close group and were inelastic enough to meet the situation. So a meeting was called by Dr. Brisbine, who was then president, the laboratory equipment and apparatus sold, the books in the library returned to the donors, and the remaining funds expended on a rather elaborate banquet, and the Academy "liquidated and dissolved." This was in 1866. During the four year period from then until 1870, informal medical meetings were held to which others than those formerly belonging to the Academy were invited. When the present State Medical Association was formed in 1869, the physicians of Ramsey County felt that the time had come to organize again, and the suggestion of Dr. Hand that it be called the Ramsey County Medical Society, prevailed. The status of the physicians of the country was then pretty well known, and our present society was formed on February 14, 1870. Who took the initiative in its formation remains in some doubt. It is certain that the remaining members of the Academy were somewhat apathetic as to starting a new society. The active organizers probably were Drs. Boardman, E. H. Smith and Flagg, urged on by Dr. Willey, who at this time was too far gone with tuberculosis to take an active part in the organization, though he was one of the active organizers of the State Society the year before. The first meeting was held in Dr. E. H. Smith's office, with Dr. Willey acting as temporary chairman until the officers and committee of organization were selected. It may be interesting here to relate the history of the seal of our society. This can best be done by quoting a letter written by Dr. Brewer Mattocks under date of October 3, 1914. Dr. Mattocks is our sole surviving charter member, and we hope will be with us tomorrow. He states: "As to the Seal of the Society, we had none until I was elected to an honorary membership on my return to St. Paul (about 1900) when I was, with the remaining charter members, Drs. Flagg, C. E. Smith and Wharton, appointed to secure the pictures of the charter members. It then occurred to me that we should have a seal, and I suggested the microscope, the pen and the scalpel with the legend dissect, observe and write, in the imperative. I wrote to Bishop Ireland to latinize the motto for me. He was kind enough to send his secretary to me with the suggestion that the imperative be changed to the infinitive, and wrote the legend as it now stands. Drs. Flagg, Smith, and Wharton united with me in presenting this seal to the society, which was graciously accepted as such, and no questions asked from the surviving charter members."

I may say, in addition to this, that the design was drawn by R. O. Sweney. No doubt many of our older members remember Sweney's Drug Store on what used to be called Bridge Square (Third and Wabasha streets).

THE RAMSEY COUNTY MEDICAL SOCIETY'S LIBRARY*

A SHORT HISTORY AND A DISTINGUISHED SERVICE RECORD

H. Longstreet Taylor, M.D., LL.D.
Saint Paul

THE SUBJECT I am to talk about this evening is one that recalls many delightful personal reminiscences, and which I most sincerely hope will please you in the telling.

The library of the Ramsey County Medical Society is now thirty-five years old. It is still growing vigorously, with every promise of a middle age whose service to the local practitioners of medicine should prove to be one of ever increasing usefulness.

We will first consider its birth and infancy, the most important period in the records of every living organism.

" 'Tis fortune gives us birth.
But Jove alone endues the soul with worth."

Dr. Jay Owens in 1883 offered the exchanges of the Northwestern Lancet, of which publication he was editor, to the Ramsey County Medical Society as the nucleus of a library. Unfortunately nothing happened.

At the annual meeting of the Society in January, 1895, the retiring secretary, Dr. H. Longstreet Taylor, made a plea that the Society found a reference medical library, and outlined a plan for its foundation and support.

Dr. A. B. Ancker, presiding, appointed, as a committee to consider the suggestion, Drs. Millard, Renz, Ohage, Foster, and Taylor. After much deliberation it was decided to establish a loan library by providing a room and borrowing reference works from the members of the society, which were to be properly housed, catalogued and made accessible to all searchers after medical truth, and also were to be returned to their owners upon demand. Lest we should forget this last clause, allow me to digress a moment to state that every one of the hundreds of volumes collected in this way is still on our shelves, while, I am sorry to say, very few of the generous lenders are with us today.

A library association was formed, with Drs. Rothrock, Dunning, Eduard Boeckmann, Auten Pine and Taylor as directors. Two rooms were secured for the library and a laboratory in the old Lowry Arcade, which space was given up for quarters in the top of the new Lowry in 1912, when history, as is her wont, repeats once more, and today we move into these palatial quarters in the newest Lowry Building, now known as the Lowry Medical Arts Building.

In the beginning, funds were supplied by the donations of the members, and books and medical journals were solicited on all hands. One of the Board made a practice of spending Saturday afternoons with an express man and his wagon, going to the residence of any physician who would give his permission, and there, with the very willing consent and approval of his wife, would go through the attic or storeroom and cart off everything in the way of medical books and journals that had gradually been crowded off the book case shelves and had finally been consigned with other dust catchers to these regions. These forays often yielded very large dividends, sometimes in unusually valuable books or a first edition, or a rare print, but always in back numbers of periodical literature, which eventually, in combination with donations of others, supplied the missing gaps required to yield complete volumes of the leading medical journals. When these complete volumes finally ran back for five, ten, or even fifteen years and began to fill the sections allotted to them, the triumphant joy of the bibliophilic collector was experienced by the members of the committee. Personally I look back upon the evenings spent with these express wagon loads of treasure, oftentimes in the congenial company of Eduard Boeckmann, sorting over the spoils of the latest raid until the wee small hours. He and I once spent a week-end in the southern part of the state, at the home of a prominent physician, recently deceased, and added a large shipment of Scandinavian literature to the library. We left the house at dusk Sunday evening in a one horse buggy, with Dr. Boeckmann driving. It soon began to rain and grew very dark. It seemed as though we were alone in the thick fog and rain, as no travelers met us, no friendly lights shone from any farm house windows, and that we were doomed to go on forever in that uncomfortable environment. The horse, however, did not agree with the driver as to the whereabouts of our destination. Dr. Boeckmann had apparently laid out a course on one of the great circles, while the horse was equally persistent in an effort to find a shortcut, which was located somewhere within the circle and to our right. The resultant of the action of these two discordant wills was that the buggy wheels would frequently sink in the cultivated soil of a wheat field, for being a grain farming region there were no fences. Then it became necessary to make ever widening circles around the horse and vehicle until the road was once more located. And so it went until at length we came to a farm house, and after much knocking and calling we were finally informed that we had circled around our objective, and, although we had started a dozen miles to the west of it, were now about as far to the east. The first streaks of dawn showed us the way to that long sought habitat of man, and the railroad station.

---

*Read before the Ramsey County Medical Society, Saint Paul, February 27, 1931.

In the fall of 1897 the Society took over the work of the Library Association. Drs. Rothrock, Morley and Taylor, the first committee, were instructed to solicit funds and secure donations and bequests, as well as to supervise the smooth working of the library machinery, with all due diligence.

Urged by the demands of this stalwart young offspring, a period of surprising and rapid development came to the Ramsey County Medical Society. It was very evident that the mounting expenses of the library could not be met by the annual dues from the members, nor by the annual contributions.

Many and various suggestions were made. The one that seemed most promising was that the Society should publish a monthly medical journal. The journal could be exchanged with the great majority of American medical journals, would receive many books from medical publishers for review, and might succeed in selling enough advertising space to make substantial financial contributions to the library. In January, 1898, a committee was appointed to consider this subject from all angles. In the fall of the year the committee not only recommended that the Society publish its own journal, but also endorsed the project, offering to assume any and all financial liabilities that might arise during the first or probationary year. While not so stated, this guarantee was made by Dr. Boeckmann to the other members of the committee in order to insure the adoption of the report by the Society. Such was the wholehearted and generous character of the service he always gave to the Ramsey County Medical Society. He never stopped to count the cost and never asked how much there might be in it for him. In this case he saw that the Society needed funds, he believed the journal would become an important contributor, he knew that many members were afraid of the venture, and in order to insure the adoption of the report he was willing to back it to the finish. He was quite right. The clause carried the report, but by a very narrow margin.

The St. Paul Medical Journal lived through nineteen years. Its publication was suspended when the Minnesota State Medical Association decided to issue its own journal. The Ramsey County Medical Society retired from the field to insure the success of MINNESOTA MEDICINE. The advertising contracts, subscription lists and so forth were turned over to MINNESOTA MEDICINE, which is now thirteen years old.

Dr. Burnside Foster was made editor of the St. Paul Medical Journal, a position he filled most creditably until his death, when Dr. E. T. F. Richards succeeded him.

Dr. Taylor was the business manager for the first ten years, when Dr. J. M. Armstrong succeeded him.

At about this time, when the struggle for the St. Paul Medical Journal was in progress, Dr. Boeckmann donated to the organization his process of making pyoktanin catgut for surgical uses. The workers from his office, who had been trained by him in the long period of experimentation it had required to perfect the product in accordance with his stringent standards, were transferred to the Ramsey County Laboratory and the Society was launched on a commercial project. The manufacture of suturing material for surgical uses was a most appropriate activity for a medical socety to engage in. The laboratory committee from that day to the present time have supervised the sterilization, cleanliness and general safety of the product, which has never been allowed to sag "one jot or tittle" from the high standards set by its originator, and consequently the venture has been crowned with success in every way.

In June, 1899, through the Medical Library Association, Dr. Rothrock reported a gift from Mr. Watkins Seamore of Troy, New York, of his father's valuable medical library of 340 volumes. From exchanges arranged by the Medical Library Association and by personal solicitations a large number of valuable books and entire sets of many journals, both domestic and foreign, were received. These donations came from medical libraries of Boston, New York, Washington, Cincinnati and other centers.

In 1904 the Ramsey County Medical Society, seeing that The Journal and the catgut had both made good, took another forward step by creating a trust fund to be known eventually as the Eduard Boeckmann Library Building Fund, this fund to be used for no other purpose than the erection of a home for the Society, with its various activities.

At the time of the foundation of this fund, Dr. Chas. A. Wheaton put into it a balance of $3,286.85, which he had carefully guarded for several years, while considering the best way to use it in the interest of the medical profession of St. Paul. It was the balance of a fund subscribed by the citizens for the entertainment of the members of the American Medical Association attending the St. Paul meeting in 1901. Dr. Wheaton had offered to refund this sum to the donors, but was told to use it for the medical profession.

This sum and the amount appropriated by the Society amounted to $6,055.62. The St. Paul Medical Journal, in addition to liberal appropriations to the library, added to the building fund the sum of $3,300.00 from 1904 to 1910.

The laboratory has always been a good provider for all the activities of the Society. Its yearly contribution to the building fund has been the backbone of that rapidly growing trust. In addition to this, the rapacious appetite of the library has received a generous slice of the catgut earnings every year, which for the period of 1904 to 1930 amounts to $22,349.00.

Dr. Boeckmann was a staunch believer in the wisdom of owning your own home, and prophesied on every occasion that eventually the society would build its own home from the profits of its suture factory. Although the fund has passed the $200,000 mark, the home he dreamed of is still in the future. The truth of the matter is that such a home should be liberally endowed, to guard against all contingencies.

The owners of the Lowry Medical Arts Building have presented the Ramsey County Medical Society with conveniently arranged and very attractive quarters on a long lease at a nominal rental, a most advantageous arrangement. The building fund should double itself during the duration of this lease.

Having thus outlined the early history of the library and the activities of the Ramsey County Medical Society which nourished it, let us glance at the achievements of a couple of latter-day saints who have contributed much to its career.

The name of Dr. John Milton Armstrong first appears on the library committee early in the twentieth century. His position as manager of the St. Paul Medical Journal gave him an opportunity to look after the interests of the library by safeguarding the continued success of that publication.

His devotion to the library knows no bounds. It has developed his talents as a book collector and has added to them those of an antiquarian interested in early types and the development of surgical instruments.

Dr. Wallace Cole, when president of the society, began the collection of old and interesting surgical instruments and appliances. Three fine cabinets filled with these specimens graced our former quarters and decorate the new one. One of these was presented by Dr. Arnold Schwyzer, one by the Miller Clinic, and one by the Earl Clinic and the St. Paul Clinic conjointly.

Among the rare books Dr. Armstrong has added to the library, two examples are worthy of mention: the Medical Repository, Philadelphia, a medical periodical, of which twenty-three volumes were published beginning in 1797; the Medical and Agricultural Register of 1806, containing the first description of epidemic cerebrospinal meningitis. The library contains also other valuable early American publications.

He is also responsible for the memorial tablets in our entrance hall. Relatives or friends of any deceased member of the society can secure a memorial tablet by making a donation to the library.

Dr. Eduard Boeckmann, our generous benefactor and wise leader, heads the list. The others in this roll of honor and the donors are:

Mrs. Frederick W. Van Slyke, for her deceased husband.

Mrs. E. J. Abbott and Mrs. C. C. Slaymaker, for their father, Dr. John Steele.

Mrs. J. C. Edge, for her husband, Dr. S. D. Flagg.

Mrs. J. W. Willis, for her father, Dr. A. Wharton.

Mrs. C. E. Smith, Sr., and Miss Mary G. Smith, for Dr. F. R. Smith, Dr. Chas. E. Smith, Sr., and Dr. Chas. E. Smith, Jr. (three generations of the family, while a member of the fourth generation, Chas. E. Smith, 3rd, is now taking the pre-medical course at Yale).

Mrs. Theodore Griggs, for her grandfather, Dr. T. R. Potts.

Mrs. F. B. Kellogg and Mrs. F. J. Ottis, for their brother, Dr. Paul B. Cook.

Dr. Harry Ritchie, for his father, Dr. Parks Ritchie.

The other heavenly twin of the latter-day saints is Dr. Frank E. Burch. It was he who succeeded in having the old Medical College Building on Ninth Street deeded to the Ramsey County Medical Society. This very desirable and valuable piece of property is now an integral part of the Boeckmann Library Building Fund.

We have a substantial inheritance from the fathers of the profession in St. Paul, men who were brave enough to begin the teaching of medicine in Minnesota many years ago.

All sciences are in a constant state of flux and change. None more so than medicine. A medical book five years old is proper fruit for the crematory.

With such a rapid deterioration the necessity for new and vigorous growth is very apparent. This explains the instructions that during the gay nineties were given to every library committee. Go forth along the highways and byways and get donations and bequests, for this library of ours is an animal with a voracious appetite and a capacity for rapid growth that must be fed, not with lime salts, but with gold.

The library at the present time has some 13,000 volumes on its shelves, and constitutes an important medical facility of the community, emphasized in the report of the committee on the cost of medical care as essential everywhere.

Miss Isabelle Anderson, A.B., B.S., a medical librarian of much knowledge, tact and experience, is in charge.

Our library books may be consulted by anyone and the medical profession of Minnesota knows that it is always welcome. The services of the attendant, the use of the study alcoves, and the most recent advances in medicine are all here and are to be had for the asking.

THE TREATMENT OF ANAL FISSURES

Harry F. Bayard, M.D.
Minneapolis

THE TREND in treatment of anal fissures veers more and more to a radical type as each individual surgeon studies his results and the basic factors in the recurrent cases. The history of the usual fissure is that of healing and recurrence; in a survey of the pathogenesis and complications the reason for recurrence becomes obvious and I hope to emphasize these factors.

Anal fissures occur in the skin just external to the mucocutaneous junction in the posterior quadrant. It is estimated that 90 or more per cent of fissures occur in the posterior anal quadrant and of the few anterior ones a predominant number will be found in female patients. Mechanical factors explain this predilection of fissures for the posterior quadrant. As the stool is contracted upon by the rectal musculature it is forced caudally with the anterior rectal wall lying almost straight and being rather well immobilized by the prostate in men and the uterus and adnexa in women.

The side walls of the rectum are limited in lateral excursion by the ischii so that as the stool passes down to the anus the posterior quadrant is the only part of the anal circumference in which much stretching may occur. This stretch occurring in the posterior quadrant, together with the curvature of the sacrum forcing the stool with a great deal of power over the posterior commissure, throws the brunt of the trauma in this location and a certain number of lacerations in posterior anal crypts are inevitable, particularly in constipated individuals where the stool is too hard and large. Infection readily occurs in this traumatized anal crypts and as the process is repeated from time to time a fissure is formed. Lymphocytic infiltration and fibrosis occurs in the base and sides of this ulcer, the edge becomes thickened and finally the ulcer heals over only to be reformed by a repetition of this sequence of events.

In such manner is the acute ulcer transformed into the chronic indolent but very painful fissure with the fibrosis and infiltration involving the sphincter, spasm results, and constipation entering the picture as a causative factor also becomes part of the vicous circle. The patient suffering from a fissure postpones passing the stool due to the pain incurred, and the longer he postpones it the more damage does the constipated stool cause. During the course of a fissure frequently a small abscess will form and burrow out under the skin either laterally or posterior to the ulcer. This may rupture back into the ulcer, in which event a blind subcutaneous tract is left, or it may rupture through the skin and leave a tract with an opening through which a probe may be passed to the fissure.

Except in their treatment, anal fissures offer the physician no problem. They are easily accessible for inspection and seldom may be confused with any other pathologic entity. Few conditions as simple as an anal fissure have been honored by the introduction of such a wide variety of remedial agents. Usually the fissure will be found to be associated with an external varicosity which will form an overhanging flap at the external margin of the ulcer, while frequently at the internal margin will be found an hypertrophied anal papilla. These three pathological entities, (1) the external varicosity or so-called sentinel pile, (2) the ulcer itself, and (3) the hypertrophied papilla, make up the typical textbook description of a fissure.

Symptoms of a fissure are rather more diagnostic than are those of most anal or rectal troubles. Recurring attacks of pain with passage of stools and amounts of bright red blood varying from a streak on the stool to a cupful occasionally, make up the patient's complaint. These symptoms will be present intermittently for years or until adequate intervention is provided. In reading over descriptions of fissures the thought impresses me that a superficial abrasion is frequently being mistaken for a fissure. These latter are best left without treatment, other than simple anal cleansing consisting of sponging the anal region gently with a piece of gauze wet with witch-hazel after each stool. There is little question but that some of these abrasions when cauterized will become true fissures. It is obvious that fissure treatment such as caustic, of one kind or another, will produce a favorable result on many of these anal abrasions and prejudice the mind of the physician against more radical treatment.

Palliative measures such as silver nitrate, phenol, the actual cautery, curettage, dilatations, anesthetic ointments and solutions all are accompanied by a high percentage of inevitable failure because they do not rid the patient of all the pathological tissue present.

Palliative treatment does not remove these tracts and recurrence is inevitable if they are left. With these facts in mind wide excision of the ulcer-bearing quadrant of the anus must be the treatment. Sectioning the sphincter is not practiced except where this muscle forms a shelf across the wound preventing free and adequate drainage externally or where the muscle is incorporated in the base of the ulcer densely by infiltration and fibrosis. In case the sphincter is so involved, just enough of the muscle fibers are cut to provide a wound with a flat, clean base which will drain well. Divulsion is not advisable in any case but a mild dilation at times is necessary.

Either low spinal or sacral anesthesia gives excellent relaxation of the anus. While sacral anesthesia is slightly more difficult to accomplish than spinal I feel it is more suitable for most rectal surgery. It is difficult to explain to a patient why, after they have been told they may start walking about after forty-eight hours, they must lie flat in bed when a spinal headache is present. However, under either spinal or sacral anesthesia 100 per cent sphincter relaxation is obtained and contraction found in the anus will be recognized as due to fibrosis and scar tissue rather than muscle spasm. This factor makes regional anesthesia of the greatest help in proctological surgery.

A surgical technic which gives good control of bleeding and is of the simplest kind has been worked out. A plain catgut suture is so placed in the mucosa just above the muco-cutaneous junction that ample length is left on each end of the strand of gut for suturing. Using this suture as a steadying guide, excision of the ulcer is started just external to the suture. The line of excision is carried laterally on each side beyond the thickened skin margin of the ulcer and a wound made which is wide enough so the edges will not approximate when sphincter activity is re-established. No effort is made to keep the wound small, the excision being carried out posteriorly to the point where one is sure the wound will remain open posteriorly after the internal part of the wound is healed. Should examination under anesthesia with a probe reveal a subcutaneous tract, sinus or abscess, the wound margin is carried wide enough to include any such tract.

Mild bleeding may be encountered along the mucosal edge of the incision; a round needle is threaded on the suture already placed in the mucosa and the mucosal edge is sutured along the point where the old muco-cutaneous border existed. This is carried out with each loose end of the suture. In this fashion bleeding is controlled and the suture line acts as a splint to keep the wound edges from drawing together. A small piece of iodoform gauze is laid in the open wound and an inch-wide gutta-percha vent left in the anus.

Last but probably most important of all the steps in the patient's cure comes the matter of postoperative attention. Hot boric packs are kept on the wound from 2:00 p. m. to 10:00 p. m. the day of the operation and as indicated after the first day. The anal drain and the gauze covering the wound are removed after forty-eight hours and the patient told he may be allowed to let his bowels move. Usually this is sufficient; should it not be, a mild laxative may be given the next evening. After each bowel movement irrigation of the anal canal with water at 110°F. through an 18 F catheter is rigidly insisted on. Daily observation of the wound is carried on so that the patient's anal cleanliness may be checked and any appropriate steps taken should healing be advancing in an inadvisable manner. Mechanically washing out the anal canal with a mild antiseptic such as pure witch-hazel at each daily call is good practice. When healing is complete the wound area should present a broad, flat, firm scar which will be found to be firmer than the normal anal margin, thus providing reasonable assurance that recurrence will not take place.

SUMMARY

Diagnosis rests on finding a rather deep ulcer with thickened edges which will usually be in the posterior midline.

Radical excision under sacral anesthesia is demanded because this eliminates recurrences.

DIVERTICULITIS OF THE COLON AND SIGMOID—ITS COMPLICATIONS AND TREATMENT*

ARTHUR E. BENJAMIN, M.D.
Minneapolis

THE real significance and surgical importance of diverticulitis of the colon is not generally recognized. It has not received the scientific attention that it deserves.

On account of the inter-relationship of diverticulosis, diverticulitis, and peridiverticulitis of the colon, they are herein jointly discussed under diverticulitis.

Nearly eighty years ago, Cruveilhier[16] described what is now known as diverticulosis of the colon, and Virchow[20] in 1853 gave a clear picture of the disease. Yet, today, the cause is not known, the disease with its complications often overlooked, and the treatment neglected.

HISTORY

Graser[9] in 1898 was probably the first to understand the nature of the inflammation, now termed diverticulitis, which involves the colon. He demonstrated that diverticula occasionally existed in several portions of the colon in one individual at the same time.

Fischer[20] in 1900, Beer[27] in 1904, and Gordinier and Sampson[8] in 1906 published articles on the disease. One of the outstanding early studies of the disease was made by Wilson, Mayo, and Griffin.[26] In this study the pathology was thoroughly analyzed.

In England, Moynihan,[17] and Telling and Gruner[25] published articles giving the X-ray findings in many cases. In France, Patel,[28] Cain, and Hillemand from 1911 to 1913 also contributed much information.

It was not until the X-ray was perfected that diverticulosis was found quite prevalent among the adult population. It was discovered that many of these diverticula caused no trouble until infection occurred, after which the symptoms occasionally became quite pronounced.

Various authors estimate the percentage of individuals suffering from diverticulosis as from 0.5 to 1 per cent, and from 12 to 18 per cent of these patients have diverticulitis. Sharples[21] says in regard to frequency of the disease, "I think, if all the individuals with diverticulitis could be collected together, and then those with appendicitis, it would be found that more have trouble with diverticula than with the appendix."

At the Mayo Clinic,[16] 26,699 X-ray examinations were made, and in 1,574 of these (or 5.89 per cent), diverticula were present. In 1,918 cases of diverticulosis, 653 had active diverticulitis.

Spriggs[22] reports on 158 patients with diverticula. Seventy-six of these were found in the descending colon, thirty in the ascending, thirty-one in the transverse portion, twenty-three in the whole colon, seven in the cecum, and four in the rectum.

In reviewing these tabulated cases, one is struck with the report of the sudden death or short period of illness of some patients. Several of these were due to peritonitis.

Spriggs and Marxner[24] found 10 per cent, in their patients examined by X-ray, showing diverticulosis.

Gordinier and Sampson[8] reported diverticula of the large intestine in sixty-four out of 8,132 autopsies in Dresden, nineteen out of 2,600 at Johns Hopkins, two out of 953 in the Bender Hygienic Laboratory, and one out of 2,382 in the Boston City Hospital. I am sure modern statistics will show a much larger proportion.

de Quervain[6] says that in a number of cases diverticula are merely postmortem findings without clinical manifestations and are often missed in the first stages at the ordinary pathological examination. At operations, they are passed by as innocent ordinary adhesions and unrecognized as diverticulitis.

CLASSIFICATION

Spriggs,[23] Case,[4] Rankin and Brown,[20] Mayo,[16] and Mailer[15] have offered various classifications of the disease according to stages, symptoms, complications, and so forth.

Inasmuch as diverticulosis, diverticulitis, and peridiverticulitis are the various stages of the same disease and may be present in the same individual at one time, a classification like the following seems sufficiently comprehensive:

---

*Read before the Western Surgical Association, Kansas City, Dec. 5, 1930.

1. Spastic colitis or prediverticulosis stage.
    a. With stasis.
2. Diverticulosis
    a. Simple
    b. With fecaliths
3. Diverticulitis
    a. Simple
    b. Ulcerative with hemorrhages
    c. With hyperplasia and stenosis
    d. With infection
    e. Perforating
    f. With malignancy
4. Peridiverticulitis
    a. With adhesions
    b. Acute obstruction
    c. With abscess
    d. With peritonitis
    e. With complications, fistula
    f. With malignancy

John F. Erdmann[7] and C. D. Overton[19] believe, from clinical experience, that the cause is congenital, as they have found protrusions along the whole alimentary tract from the esophagus to the rectum.

Pieth, Patterson, Graser, Schreiber, Wilson, and many others believe that weak areas occur in certain portions of the colon preceding diverticulosis.

E. T. Bell[2] believes that congenital weakness of the muscle walls and manner of blood supply are causative factors.

C. D. Harrington[11] reports a case where a diverticulum protruded into the pelvis from the rectum back of the uterus.

Between the mesenteric and lateral muscle bands, the blood vessels penetrate the inner circular muscular fibers to enter the submucosa just before they reach the longitudinal bands on either side of the colon, constituting weak places in the bowel wall (Fig. 1). The fat epiploic appendages lie between the longitudinal bands laterally, and into these the hernia forces its way along the blood vessel entering the tag. The diverticulum is often concealed by these fatty tags.

W. D. Haines[10] calls attention to the fact that the upper portion of the sigmoid has a short mesentery and is covered with peritoneum only on the anterior and lateral surfaces in 90 per cent of cases.

Age has much to do with the production of diverticulitis, as most individuals suffering with the disease are found to be above forty-five. The disease is probably more prevalent in persons around fifty or beyond. At this time in life, individuals follow more sedentary habits, and, consequently, the peristaltic action of the intestine is less vigorous and the muscle tone is generally less positive. A sclerosis of the vessels referred to above is a potential cause.

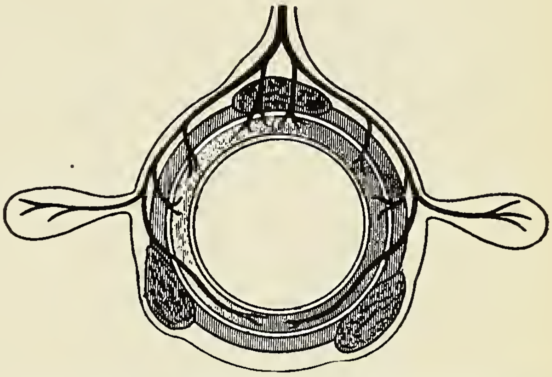

Fig. 1. Drawing showing where the muscular coat is pierced by the blood vessels from the mesentery, constituting the seat of election for diverticula (after Drummond). From Robert Mailer, The Lancet, July 14, 1928.

Robert Mailer[15] gives the following age and sex incidence:

In 100 cases of diverticulitis

Age	M	F	Age	M	F
20 to 30	0	1	50 to 60	25	11
30 to 40	6	4	60 to 70	19	5
40 to 50	17	8	70 to 80	3	1

John W. Keefe[14] states, "Diverticula occur twice as often in males as in females, and 60 per cent of diverticula have serious sequelæ." My own cases show about an equal number of diverticula in both sexes.

The anatomical arrangement of the colon, and its physiological function in which there is a slowing up of the contents of the bowel, leads to a stagnation in certain areas. Especially is this noticeable in the sigmoid, where the content becomes more firm, causing pressure and lowered vitality of the tissue.

A. C. Jordan[12] states that colitis is one of the most common causes of diverticula. On the other hand, Case[4] is of the opinion that colitis is the result rather than the cause of diverticulitis. It is reasonable to suppose that a colitis might lessen the resistance of vulnerable points in the colon and predispose the areas to diverticulosis.

Constipation is believed to be an important factor in diverticulitis.[26] Hardened fecal materials produce ulceration, and it is believed that the sigmoid, therefore, is the most commonly affected.

Perhaps the character of the food of humans, the mode of living, and habits have much to do with the cause of diverticulitis. Coarse foods do aggravate it. A reasonable amount of outdoor exercise, such as golf, is beneficial in the early stages.

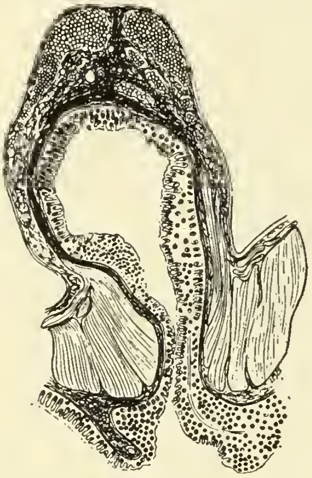

Fig. 2. The same as Figure 1.

Dr. C. P. Fitch, Chief of the Division of Veterinary Medicine, University of Minnesota Agricultural College, reports in a special communication that diverticula are occasionally encountered in the large bowel and colon of the horse due to hard balls of feces. They are found less often in cattle, but occasionally in dogs, due to pressure of a foreign body.

SYMPTOMS

Some of the following symptoms are present in each case of diverticulitis. A typical case may experience most of them up to the serious or complicating stage.

1. Increasing disturbances from gas in the intestine.
2. General abdominal distress and pain.
3. Constipation.
4. Pain in left iliac region.
5. Bladder discomfort and frequency.
6. Occasional diarrhea.
7. Nausea and vomiting.
8. Pain in rectum.
9. Passage of blood.
10. Gradual loss of weight.
11. Acute attacks of pain with fever and chills.
12. Acute obstructive symptoms.
13. Acute perforative symptoms.

Pain and tenderness may be general when several diverticula along the colon become inflamed.

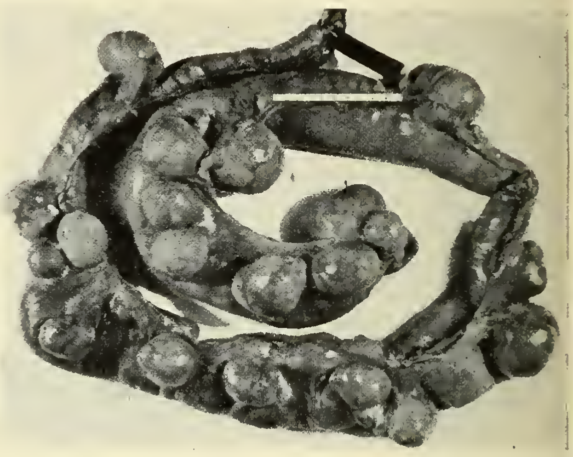

Fig. 3. Multiple diverticula of the colon. From Dr. E. T. Bell's Textbook on Pathology.

Localized soreness with a palpable mass is often confined to the sigmoid. The temperature, pulse, and leukocyte count usually rise in acute attacks, and the symptoms are occasionally mistaken for an attack of acute appendicitis.

Where a peridiverticulitis has occurred, obstructive symptoms not infrequently supervene and, when there is a history of declining health and the passage of some blood, cancer is often suspected.

Judd and Pollock[13] observed blood in 18 per cent of cases of diverticulitis and 47 per cent of those of carcinoma.

Carcinoma may be present in the same case with diverticulitis. Mayo[16] reports 15 per cent present. Ballin[1] is of the opinion that carcinoma may follow diverticulitis. Therefore, a suitable operation should be performed if carcinoma is suspected.

Rankin and Brown[20] report, out of a series of 227 cases of diverticulitis, only four associated cancer cases, and in 679 cancer operative cases, diverticulosis was found in four only.

DIAGNOSIS AND COMPLICATIONS

Before the advent of the X-ray, the profession made little headway in the diagnosis of diverticulitis. Many diverticula are missed today due to their position, or to their orifices being occluded or too small for the barium to enter. Owing to careless or imperfect technic, or lack of knowledge and experience of the technicians or interpreters, a negative report may be given. Diverticula may retain the barium many days, demonstrating how long enteroliths may remain in some diverticula. Case[14] reports one individual who had multiple diverticula which were still filled on the sixteenth day. Others reported even longer periods.

Perhaps the disease which is most frequently confused with diverticulitis is acute appendicitis. A periappendicular inflammation due to an adherent infected diverticulum can easily be mistaken for an ordinary appendicitis.

A cystitis has led many clinicians astray. They have not always recognized the cause as arising from an abscess of a diverticulum and bladder infection therefrom. Likewise, prostatic symptoms in the male as well as bladder pressure and discomfort in both sexes can originate in a diverticulitis of the sigmoid. A tumor in the left pelvis in the female does not often lead the ordinary practitioner to seek its origin in an inflammation of the sigmoid. No doubt, some are operated upon and an adherent tube or ovary is removed with the diagnosis of salpingo-oöphoritis.

An attack of diverticulitis may be mistaken for a volvulus or vice versa. Pancreatitis, gallbladder disease, intussusception, or tuberculous peritonitis can be confused with diverticulitis. So-called abdominal adhesions are operated upon as frequently as any other condition without the knowledge that they may be nature's barrier preventing a perforating diverticulum from infecting the peritoneal cavity.

Old abscesses, originating from perforating diverticulitis where pus has traveled to remote corners of the abdomen and opened elsewhere, may be very difficult to trace. Backache, sacro-iliac discomfort, and many unfathomed neuralgias and pains may, in the future, be traceable to diverticulitis in some cases. An ischiorectal abscess unquestionably is frequently due to diverticulitis of the lower sigmoid or rectum.

TREATMENT AND PREVENTION

It is probable that fewer cases of diverticulosis and diverticulitis will develop in the future on account of the careful supervision of diet habits of children by the pediatrician.

A case of diverticulitis should constantly be kept under observation and treated to avoid the inflammatory stage, if possible. Perhaps the selection of proper diet, colon irrigations, and olive or mineral oils may assist in preventing diverticulitis. Exercises in which the abdominal muscles massage the intestines are beneficial in assisting the diverticula to empty, and favoring regular normal evacuations.

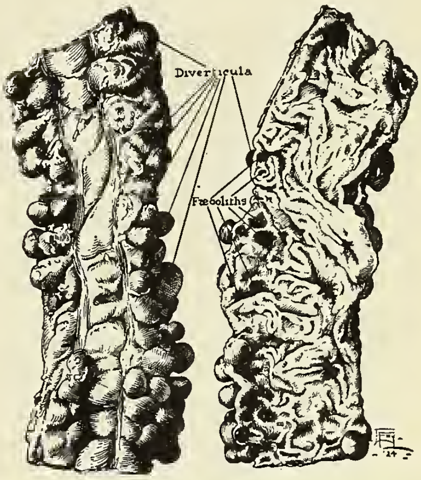

Fig. 4. Multiple diverticula of the descending colon filled with feces. From Rankin and Brown's article on "Diverticulitis of the Colon," S., G. & O., April, 1930.

When a surgeon is confronted with symptoms of impending perforations, peritonitis or obstruction, it is his duty to institute surgical relief early. A late operation may be unsatisfactory, imperfect, or useless. When the operation is performed early, before the patient is in a serious general condition, the diverticula may be inverted, the region drained, or the bowel resected, perhaps with satisfactory results or without serious consequences. A preliminary colostomy in severe obstructive cases is the operation of choice, and this may be done by bringing the descending colon, above the obstruction, partly out through the abdominal wall, passing a fascial strip through the mesentery for support. Later, when the patient is in good condition, the bowel may be resected, unless the infection and obstruction disappear. The bowel may then be replaced within the abdomen by cutting the fascial strip, separating it from the wall, and allowing it to drop back. The colostomy can be closed later. A side anastomosis can be performed, if preferred, excluding the obstructed area, and, by leaving the colostomy open temporarily, undue tension on the enterostomy stitches is prevented.

On account of the frequency of carcinoma associated with diverticulitis, resection should be performed in suspicious cases, even though the obstruction may not be complete.

Overton[19] states that we may expect 90 per cent cures in diverticulitis by early expert surgery.

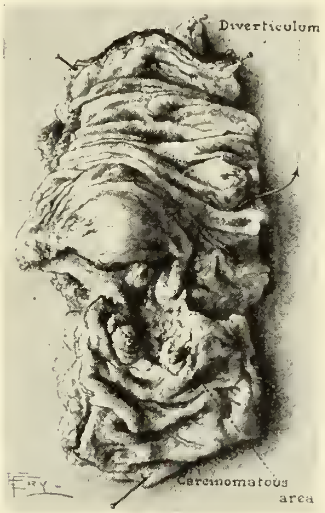

Fig. 5. Carcinoma of the colon developing in the presence of a diverticulum. From Rankin and Brown's article on "Diverticulitis of the Colon," S., G. & O., April, 1930.

Bensaude and Hillemand[3] prefer a colostomy if a removal of the mass is impossible.

Gerzowitsch gives a mortality of 12 per cent in a series of sixty-one cases resected.

When the disease is confined to a known area or section, resection is the choice where possible, but a resection performed when other nearby tissue harbors diverticula that are infected courts disaster. A colostomy may save the patient and permit a later safe radical curative operation.

CONCLUSIONS

1. As a possible focus of infection, diverticulitis is often overlooked.
2. The location and direction of the lateral blood vessels of the colon and sclerosis of these vessels may predispose to herniation.
3. Congenital weakness or defects in the colon wall are recognized possibilities.
4. Age, obesity, and sedentary habits may favor the development of diverticula.
5. Improper habits and unsuitable food may account for their unusual frequency in humans as compared with that of other animals.
6. Symptoms caused by diverticula are misleading and sometimes attributed merely to indiscretion in diet.
7. The diagnosis can and should be made early, by means of an X-ray examination.
8. Treatment should be directed toward preventing further progress of the disease when possible.
9. Operations for diverticulitis and its complications include some of the most formidable surgical procedures known. Experience, judgment, and skill are necessary to obtain the maximum results.

The following will illustrate a few of the cases of diverticulitis that are encountered, some with severe and acute symptoms as well as complications.

CASE REPORTS

Case 1.—Perforation of Diverticulum and Sudden Death.

Mr. O., a widower, aged 68, and a laborer, had complained for some time of gas and occasional pain in the lower left abdomen. While going to work one morning he was seized with pain in the lower abdomen. He dropped to the ground as though shot and was picked up in a very weak condition. When he arrived at the hospital he was pale, had an irregular and weak pulse, and was in shock. He showed evidence of some acute abdominal condition.

He was given stimulants and hypodermoclysis, and was operated upon. We found a perforation of a diverticulum of the sigmoid with the contents of the bowel in the pelvis. He gradually failed and died the next day, apparently from the effect of shock.

This case demonstrates the serious consequences that may arise in a case of diverticulitis.

Case 2.—Diverticulitis with Infection, Obstruction, Abscess and Pelvic Peritonitis and Pneumonia.

L. A. L., a male, aged 57, had been sickly as a child but quite well after the age of twenty, except for attacks of tonsillitis. He had a small left hernia repaired in 1915 and had had an attack of sciatica in 1919. He states that he has had some prostatic trouble of late and used to have considerable backache when younger. He has had pain in his right side and back for a month and an acute sciatica and backache for over two weeks.

The patient was taken suddenly ill on the morning of January 10, 1922, with pain in the left inguinal region, the pain radiating upward with some general abdominal discomfort, considerable nausea, retching and vomiting. The patient became very restless and extremely thirsty. Temperature ranged from normal to 99.2. The pain became less in the afternoon and his temperature became normal. The leukocyte count ranged from 13,000 to 17,000 the first two days in the hospital. His bowels moved on the first day after an oil enema and later after a low modified *Noble's* enema. The evening of the next day he became worse, with increased pain and vomiting. The abdomen was somewhat distended, and a mass with dullness was present above Poupart's ligament on the left. On account of the increased severity of the symptoms and suffering, an operation was performed on the second evening.

A left rectus incision was made under local anesthesia. A mass of adhesions was present around the sigmoid with marked diverticulitis. Numerous diverticula containing fecal concretions were found. The lymphatics were enlarged. Some of the fecaliths were forced back into the bowel through the openings, and the diverticula ligated. Owing to the extensive involvement of the bowel, resection was thought inadvisable. A Penrose drain was placed in the region of these adhesions.

The patient progressed satisfactorily for a few days. He had some hiccoughing and vomited occasionally. Gastric lavages relieved the vomiting. His abdomen became less distended and he was able to retain some nourishment. There was more or less drainage from the wound. He, however, developed an obstruction later necessitating a colostomy, which improved his condition somewhat. A bronchial pneumonia supervened, however, and he died, February 1, twenty days after the acute abdominal symptoms began.

Case 3.—Diverticulitis with Diseased Thyroids, Fibroid Uterus.

Mrs. A. R. P., aged 53, had had a radical operation for cancer of the left breast in 1911. Ligation of the inferior and superior poles of the thyroid had been done in 1911. The patient had been very nervous and had had more or less pain in the left abdomen, but no nausea or vomiting. There had been some diarrhea at times; dysuria and disturbed vision.

Examination showed the thyroid, especially in the region of the isthmus, markedly enlarged. There were fibroids of the uterus with retroversion. A few hemorrhoids were present.

On account of toxic symptoms, a thyroidectomy was performed and five-sixths of the thyroid lobes was removed. Progress was satisfactory as far as the thyroidectomy was concerned, but the patient still continued to have pain and abdominal distress.

X-ray examination showed several diverticula in the descending colon and sigmoid. There was no evidence of diverticulitis, obstruction or new growth at this time, but a prolapse of the transverse colon was evident.

The uterus was enlarged to twice its normal size, retroverted and contained fibroids. The appendix was retrocecal and fixed. An appendectomy and a supravaginal hysterectomy were performed.

The patient made a satisfactory recovery from the operation but still complains of constipation and abdominal distress. The bowels move every other day, but she has some abdominal distress and distention if she is not careful about her diet or eats too much. She gets tired and nervous at times, but looks much better. She is more energetic, has a better color, and has gained slightly in weight. We do not expect this patient to become perfectly well, but care in her diet should prevent her diverticulitis from growing progressively worse.

Case 4.—Acute Bowel Obstruction from Diverticulitis.

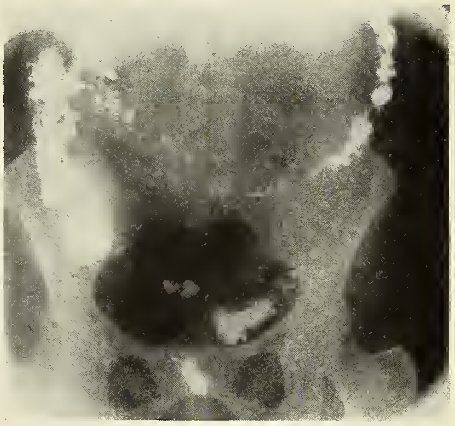

Fig. 6. X-ray of colon (Case 5) showing multiple diverticula.

Miss D. C., aged 42, had always had good health until a month previous to examination, when she began to be troubled with extreme constipation and marked abdominal distention, followed by nausea and vomiting and symptoms of acute obstruction.

At operation, some adhesions were found around the gallbladder. The cecum, ascending and transverse colon were greatly dilated and complete obstruction was found at the lower portion of the descending colon, annular in type. The descending colon was separated and a loop brought up into the wound. It was anchored to the peritoneum and a fascial strip passed through the mesentery of the bowel for support. A tube was stitched into the bowel. Microscopic examination of tissue removed showed no cancer, but an acute inflammation from diverticulitis, with ulceration.

Progress was satisfactory excepting that the blood supply was somewhat interfered with. About two inches of the obstructing portion sloughed and a considerable drainage occurred. The obstructing and sloughing area was removed by cautery at a later date.

A second operation was performed to unite the lower and upper rectal colon. Many adhesions were separated and a side anastomosis of the distal and proximal portions of the colon was made. The former opening was left for a vent.

Since that time there has been some drainage and a few fistulæ, originating from the site of the anastomosis. She now has a small fistula and there is a little fecal discharge occasionally from the colostomy opening, but she has a normal bowel movement daily. The remaining fistula can be closed as soon as the inflammatory trouble disappears and the tissues are in condition for the repair work.

Case 5.—Multiple Diverticula of Colon with Perirectal Abscess.

Mrs. B., aged 63, a nurse, had suffered from gastrointestinal disturbance for years. Diverticula were discovered about fourteen years previous (Fig. 6). She has had marked constipation, considerable dysuria and frequent micturition, occasionally passing some blood from the bowel. She had had perirectal abscesses in 1927 and fissures for some time. The abscess was apparently due to diverticula of the rectum. She was operated on in 1927 with drainage and good recovery. Hypertension has existed for a number of years.

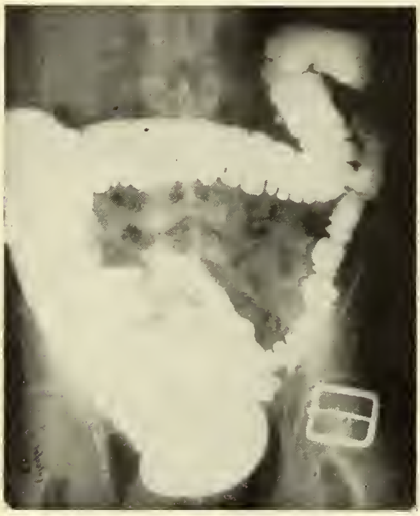

Fig. 7. X-ray of colon (Case 7) showing diverticulitis of the transverse colon and spasticity.

Gastrointestinal symptoms have become considerably less and she is in fairly good general health. She has no trouble with the rectum. She has lost about fifteen pounds in weight during the last five years. Hypertension is still present.

Case 6.—Diagnosis of Cancerous Growth in Pelvis, but Probably Due to Diverticulitis.

L. H., a housewife, aged 71, had suffered from extreme constipation, gradual loss of weight, nausea and vomiting. Her weight was about eighty-seven pounds and her previous attendant had diagnosed cancer in the pelvis.

Upon examination the colon was found to be greatly dilated, giving the impression of a cyst in the pelvis. There was a prolapse of the uterus with some cystocele and rectocele. A tympanitic note was present over the cecum, transverse and upper portion of the descending colon. No solid mass was found in the pelvis but there was a slight dull area in the region of the sigmoid. The urine showed a trace of albumin and sugar, and clumps of pus cells. The hemoglobin was 75 per cent. X-ray showed an enormous dilatation of the entire colon as far as the sigmoid. A barium enema was not retained because of obstruction in the upper part of the rectum. Examination by sigmoidoscope showed no ulceration or growth.

On August 1, 1930, under local anesthesia, a colostomy was done, bringing a loop of the descending colon up and out of the abdomen, using a fascial strip through the mesentery of the colon for support, and inserting a rubber tube into the colon through which frequent irrigations were done to empty the colon and reduce its size. The colon above the obstruction was greatly dilated. A small mass in the region of the sigmoid, due to inflammatory trouble in and around the sigmoid, like a diverticulitis and not like cancer, was found. A specimen removed failed to show carcinoma. The patient began to improve, and gained in weight and strength. The colostomy opening functioned perfectly. She is up and about, able to wait on herself, get her own meals, and seems quite well generally. The colon is reduced two-thirds in size so that the tympanitic note has disappeared. The abdomen remains flat. The bowels frequently move normally.

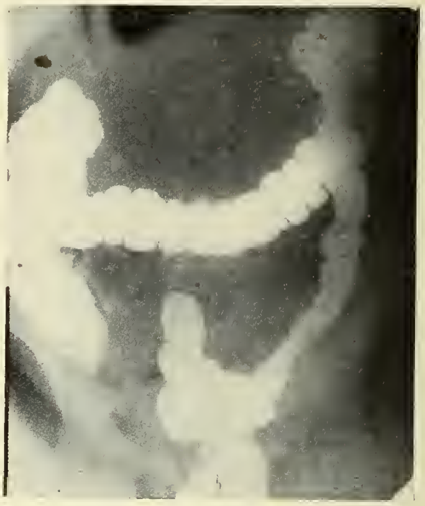

Fig. 8. X-ray of colon (Case 9) showing narrowing due to peridiverticulitis.

Case 7.—Diverticulitis with Chronic Indigestion.

Mr. D. C., aged 58, has had indigestion, belching of gas, constipation, abdominal distention and soreness along the transverse and descending colon for a number of years. He has passed some blood occasionally.

X-ray showed diverticulosis and diverticulitis of the transverse colon and sigmoid (Fig. 7).

Special diet, mineral oil, oil enemata, bowel flushing, and moderate exercises have lessened the distressing symptoms and resulted in much improvement. He passes little or no blood now but has moderate distress in the abdomen at times.

Case 8.—Possible Diverticulosis.

C. J. D., aged 47, a bond salesman, weighed 190 pounds and was 5 feet, 9 inches tall. He had had a double herniotomy in 1910, and tonsillectomy and adenoidectomy in 1918. He had also had influenza and the usual children's diseases. He has had more or less gastrointestinal disturbance, with pain in the region of the appendix.

In November, 1929, he had an attack of appendicitis and was operated upon. Previous to that time he had

had some trouble with flatus, hyperacidity of stomach, and some nausea. Several adhesions in the lower left abdomen were found at operation.

A barium enema before appendectomy showed several diverticula in the pelvic colon and some spasm of the tip of the cecum. The urine showed a heavy trace of albumin, and a large trace of sugar, but this disappeared while he was in the hospital. In February, 1930, he had an acute cold, a leukocyte count of 10,500, and a trace of albumin in urine. About this time he began to have more or less dizziness, bloated abdomen, and some headache. Diet, bowel flushes, oil enemas, etc., caused gradual improvement.

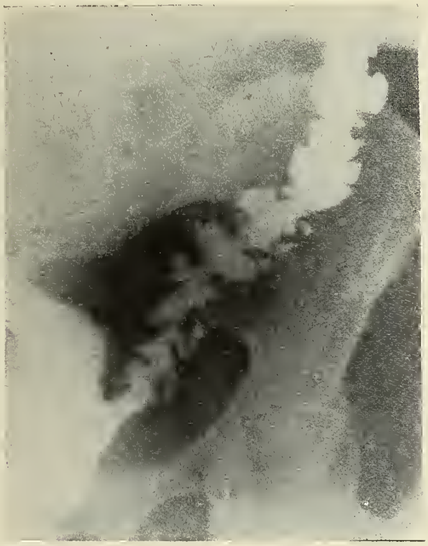

Fig. 9. X-ray showing multiple diverticula of the descending colon without symptoms.

At present he is feeling very well, the dizziness has about disappeared, except when lying on his back.

Case 9.—Diverticulitis and Peridiverticulitis.

H. L., age 68, a female, gave a history of hemorrhoids, abdominal distress, with pain, general discomfort and constipation, dysuria, and pain in the back. In 1925 the hemorrhoids were removed. Later a proctoscopic examination revealed some redness and inflammation in the upper part of the rectum, from which area there was slight bleeding.

X-ray revealed diverticula of the sigmoid and lower portion of the descending colon (Fig. 8). There was an inflammatory exudate in these areas, partly constricting the colon. The patient progressively grew worse and developed obstructive symptoms.

On February 6, 1929, a laparotomy was performed. The sigmoid was entirely involved and almost completely obstructed, the descending colon fixed by numerous adhesions. A colostomy was done above the obstructed area. A fascial strip was passed through the mesentery of colon for support, a Penrose drain placed in the region of the infected diverticula and a tube was stitched into the colon. The patient progressed favorably, but developed an abscess which extended to the right side of the abdomen, and was later opened and drained. The gallbladder was very much enlarged and adhesions were pronounced in that region. Bladder symptoms were quite aggravated during all this time and considerable pus was found in the urine. Cystoscopic examination showed a definite cystitis.

Convalescence was rather stormy but gradually the patient improved and with the exception of a somewhat narrowed colostomy opening and a post-operative hernia she is in fairly good health. She occasionally has some fecal passages per rectum. All inflammatory trouble seems to have disappeared, as well as the bladder discomfort.

THE WHOOPING COUGH PROBLEM*

L. W. Sauer, M.D., Evanston, Illinois: The etiology, the mode of dissemination, and the laboratory diagnosis of whooping cough are well established. It is the most prevalent communicable disease of early childhood, mainly because it is customary to procrastinate about diagnosis and quarantine until the whoop has developed. As in measles, the most contagious period is the catarrhal stage, that is, before the clinical symptoms are typical. To make an earlier diagnosis mother and physician must become "whooping cough minded." The cough plate of Chievitz and Meyer is comparable to the culture for the diagnosis of diphtheria. The plate must be exposed relatively early and must be well coughed on; it requires three or fours days' incubation. Patients do not always exhale pertussis bacilli. A child may have typical paroxysms without expelling pertussis bacilli on the plate. It is best to expose plates in duplicate. A negative plate does not exclude pertussis.

Leukocytosis, especially lymphocytosis, characterizes the spasmodic stage, but is usually absent early in the catarrhal stage. The earlier in the course of the disease, the less characteristic the cough, and the lower the blood count, but the more likely will the cough plate be positive; the farther along the disease, the more typical the cough, and the higher the count, but the less likely will pertussis bacilli be isolated. The mortality rate is 1 per cent of the cases for all ages; it is 33 per cent of the cases when computed for infants aged less than one year.

Fresh, not cold air, proper food and aseptic nursing care are essential; quinine, phenobarbital and ether by rectum are valuable adjuncts which help give symptomatic relief. Vaccine, as used at present, is of doubtful therapeutic value.

A PROPOSAL OF WHOLESALE PASSIVE IMMUNIZATION AGAINST POLIOMYELITIS EPIDEMICS*

J. Charnley McKinley, M.D., Ph.D.
Minneapolis

The writer feels some trepidation in putting the following suggestion into print because he has developed his point of view only through apparently logical deductions from premises which have not been sufficiently clearly demonstrated to permit classing them as established facts. It must not be thought, therefore, that wholesale passive immunization will surely be even a partially suitable weapon against poliomyelitis. But the ineffectiveness of our present attempts to stop the spread of epidemics of this disease is sufficient excuse for a presentation of this sort, and justifies the advocacy of any reasonably promising public health procedure, provided that the measure is not prohibitively expensive of time and money, and provided that it will conceivably do no harm. This paper then is nothing more than a plea for the trial of an experiment that might work as desired.

After the writer's own ideas were well systematized previously to writing this paper, he found a short article by Moro,[1] with essentially the same proposal as is here presented. Also, during the preparation of the manuscript, a paper by Flexner[2] appeared, in which he dwells in a few paragraphs on the possibly desirable effect of the same means of attack as is here outlined.

Let us consider the premises on which this proposal is based. The first four are the result of long series of investigations, both experimental and clinical. They have been discussed repeatedly in the various monographs on poliomyelitis; hence no attempt will be made in this paper to give credit where credit is due. The fifth one revolves about the recent experimental work of American investigators, which is especially significant, and will receive special treatment. The premises follow:

1. The usual incubation period of poliomyelitis varies between four or five to eight or nine days. In a series of about 200 cases of monkey poliomyelitis induced experimentally in previously untreated animals at the University of Minnesota, the longest time interval was 22 days. Incubation periods of more than two weeks in our experimental animals have been rather exceptional.

2. An attack of poliomyelitis confers regularly a strong, lasting immunity. The extreme rarity of two attacks in the same individual is evidence for this point. Further, it is difficult to produce the disease in a monkey that has recovered from a previous attack.

3. The blood serum from a person or monkey that has had a previous attack of poliomyelitis will inactivate the virus. If such an immune serum and a potent virus are mixed in the test tube and a portion of this mixture is injected cerebrally into a monkey, the animal either will develop no poliomyelitis, will have a light attack, or will develop the disease only after an abnormally prolonged incubation period.

4. The blood serum from a person or monkey recovered from a previous attack apparently contains antibodies which will produce passive immunity in another animal. Thus, if this immune serum is injected into a susceptible monkey and then, within a few hours or days of time, the animal is inoculated cerebrally with active virus, the animal will be partially or completely protected against the inoculation. The length of time this passive immunity lasts is not known. An experiment is already under way for the elucidation of this point in the writer's laboratory. By analogy with other conditions in which passive immunity can be produced, this period probably extends other several weeks of time; it would thus be expected that the period will be found at least as long as, or likely longer than, the incubation period of the disease.

5. Aycock and Kramer,[3] Shaughnessy, Harmon and Gordon[4] and Schultz and Gebhardt[5] have tested the serums of normal individuals who give no history of a recognizable attack of poliomyelitis. The method of testing was to draw blood from these persons and discover whether this blood would neutralize virus *in vitro* as stated in premise three above. Neutralization

---

*From the Division of Nervous and Mental Diseases, University of Minnesota Medical School, Minneapolis.

was taken as evidence of immunity. Their work tends to show that seventy-five or eighty per cent of adults living in the larger urban communities possess blood serum with relatively large amounts of poliomyelitis antibodies and that these people are apparently actively immune to the disease. In the rural communities the immunes constitute probably half of the adult population. The assumption has been made that these normal immune adults have acquired their immunity by one or more contacts with the virus which, for some unknown reason, resulted in immunization, rather than in an attack of the disease.

The experiments of these students of poliomyelitis have to do with a number of cases which is altogether too small for definite conclusions statistically. But their work is strongly supported by the fact that relatively few persons are attacked by the disease after adolescence, and as the age grouping is increased after the first decade, the incidence of the disease rapidly decreases. In the great New York epidemic of 1916,[6] for example, 95 per cent of the cases occurred during the first decade and only 0.3 per cent of the cases occurred after forty years of age. Hence, it is extremely probable that the vast majority of normal urban adults and a somewhat smaller number of those in the country are immune in the same way that recovered cases are immune. The normal adults in a community thus constitute a large reservoir of antipoliomyelitic serum.

The problem then becomes one of making use of this reservoir. It is impractical to test these people individually to determine which ones are immune because of the necessity of using monkeys for the biological test and the extreme expense that would be involved in the large number of animals required. One hesitates to use serum picked at random from unselected adults for the specific treatment of a diagnosed case of the disease because of the chance that the donor's blood might come from the non-immune group. One does not care to gamble with percentages in such a case; and this is usually not necessary because there are nearly always enough recovered cases in a community or individuals who have previously been definitely in contact with poliomyelitis to permit their selection as donors for the developing cases that need immune serum treatment. But for a prophylactic public health measure we are entirely justified in working with percentages because it is well known that epidemics, of smallpox, for instance, can be brought under control by measures which make no pretense of building up resistance in one hundred per cent of the population.

Suppose, then, that in the presence of a beginning epidemic in a city, we were to take blood at random from the adult population and inject it in proper amounts into the members of the most susceptible age groups, that is, into children from one to twelve or thirteen years of age. The goal would be to inject as many susceptibles as possible within the shortest possible time to obtain a maximum effect of passive immunity for a given interval of time, thus reducing the amount of soil on which the epidemic could thrive. The simplest way to do this is to take parents as the donors and inject their own children with the parents' blood or with serum prepared from this blood. This avoids the necessity of setting up a laboratory technic to prevent the transmission of syphilis, though the possibility of a parent acquiring syphilis after the birth of the child must be kept in mind.

It follows reasonably well from the five premises presented in the foregoing that such a procedure would actually immunize a large percentage of the susceptibles in a community, and that, if the injections were completed within a few days, enough children would be able to resist invasion of the organism for a sufficient time so that the epidemic would lose its foothold and die out before the period of passive immunity would be lost. Further, it is logical that many of these children might accidentally come into contact with the virus during the period of immunity and be immunized actively and permanently by this contact without ever developing a clinical attack of poliomyelitis. Rhoads' work,[7] in which he was able to produce active immunity in monkeys by the injection of mixtures of immune serum and active virus, is suggestive that this desirable result might well be obtained.

Let us now attempt to make a measurement of the probable effectiveness of our passive immunization. It is necessary to assume that our reasoning up to this point is correct. Let us likewise assume that eighty per cent of the adult urban population taken at random would be found immune, as discussed under premise number five. If, then, for each child whom we wish to immunize in a large series of cases, we were to select an adult at random as the donor, the chances are that we would immunize eighty per cent of the children in the community. This in itself would be a very satisfactory result from an epidemiological standpoint, but we can do considerably better than this without adding greatly to our trouble. Let us consider the chances of immunization if we take the blood from two adults (father and mother) and inject the mixture from both into the child. Obviously the chances are that in some families both father and mother will be immune, in others either the father or the mother will be immune, and in some, neither father nor mother will be immune; the calculation of the chances of each of these combinations occurring is easily done arithmetically.

Jones[8] states the proposition mathematically as follows: "Thus to get the probability of a double success for a combination of two independent events, we must multiply together the separate probabilities for the success of each event taken by itself." In our case the chances are eighty in one hundred (80/100) that the father is immune; the chances are likewise eighty in one hundred (80/100) that the mother is immune. If we select a family at random then and wish to know what the chances are that both parents are immune, they will be $80/100 \times 80/100 = 64/100$, *i.e.*, 64 in 100.

Similarly, if we wish to know the chances of the father being immune and the mother non-immune, they will be $80/100 \times 20/100 = 16/100$.

The chances of the mother being immune and the father being non-immune are $20/100 \times 80/100 = 16/100$.

Adding together, then, the above results, for it is evident that a family cannot be simultaneously in more than one of these groups, it follows that there are 96 chances in 100 $(64/100 + 16/100 + 16/100 = 96/100)$ that one or the other of the parents, or both of them, are immunes if we select at random a family out of the general urban population. Conversely, there are only four chances in one hundred that the parents in this family will both be non-immunes.

Since the writer is not particularly trained mathematically, he gladly followed the suggestion of a University of Minnesota mathematician that these figures be put to an empirical test with a deck of cards, as follows.

The black cards were taken to represent males; the red cards, females. The twenty black cards numbered from one (ace) to ten were considered immune males; the similarly numbered red cards, immune females. Five of the black face cards represented non-immune males; five of the red face cards, non-immune females. Thus we had the character of immunity represented in the proportion of eighty per cent in our cards. The red and black cards were shuffled separately and were then laid on the table in pairs of one black and one red card each, thus representing married couples. To test our foregoing calculations it was then merely a matter of counting the number of times in a sufficient series of trials that (1) a black numbered card was paired with a red numbered card, (2) a black face card, with a red numbered card, (3) a black numbered card, with a red face card, and (4) a black face card, with a red face card. Arbitrarily, we repeated these trials until we had made up 625 couples. The percentage incidence of each group was then calculated with the result in immunological terms that:

1. The character of immunity occurred in both mates in 64.16 per cent of the pairs, as against the expected figure of 64 per cent.
2. Immunity occurred in the male but not in the female in 15.68 per cent of the pairs, as against the expected 16 per cent.
3. Immunity occurred in the female but not in the male in 15.84 per cent of the pairs as against the expected 16 per cent.
4. Immunity occurred in neither the male nor the female in 4.32 per cent of the pairs as against the expected 4 per cent.

This is sufficiently close correspondence of the theoretical and empirical figures to satisfy any reasonable objection raised against the technic of the calculation. It is clear, then, that if 80 per cent of the parents are immune, the chances are 96 in 100 that one or both of the parents in a given family will contain poliomyelitis antibodies and theoretically we should expect to immunize about 96 per cent of the children treated.

One might object that the figure of 80 per cent is too high. This cannot be disproved, but one is to be reminded that the clinical evidence on the age incidence of poliomyelitis is strong that the percentage of immune adults is actually high. If we substitute 60 per cent for 80 per cent and make our calculations, it will be found that the chances are 84 in 100 that one or both parents in a family will be immune. For the rural population, in which half of the adults have been assumed to be immune, our calculation would give us chances of 75 in 100 that the families will have parental immunity on one or both sides. This percentage would still probably be effective in combating an epidemic.

Now let us try to visualize the actual handling of an epidemic by these means.

The first point is that, since the efficacy of the procedure is uncertain, there should be provided a mechanism for keeping records on which to base future studies of the cases presumably immunized. For the first several trials, it is of extreme importance to the public and the medical profession to make as extensive a study of the situation as money will permit, so as to discover, if possible, the facts that will guide our steps in future epidemics. In the long run this will save money and effort.

In the second place, the procedure should be undertaken by the various interested groups coöperating to assure the smooth functioning of the program: State Board of Health, local health board, the local physicians, and, not least to be considered, the public in the affected vicinity. The State Board of Health has its finger on the general poliomyelitis situation in the state and surrounding states and routinely collects statistics of the sort which should be available in a situation of this kind. The local health board carries considerable responsibility in the community, and, with the physicians, would be able to assure the public that the measures instituted are as much in the interests of public welfare as they are for the intellectual exercise and academic amusement of the scientists who are likely to look on with the avidity of men watching an experiment in the physiological laboratory. The coöperation of the local physicians is further needed in the large amount of work in serum collection and injection that one would expect under these circumstances. Without the coöperation of the public in the vicinity, the plan is a failure before it gets under way. Here is one set-up in which full publicity should be given by newspapers and similar means as to the seriousness of the local poliomyelitis situation in order to bring people in for the prophylaxis within a short period of time. Consideration of local commercial interests which sometimes bring pressure to bear in suppressing such facts in order not to disturb business, would tend towards insufficient coöperation on the part of the public, and probably seriously hinder the effectiveness of the measures. In several of the universities of the country there are men especially interested in the poliomyelitis problem. These men might well be used in an advisory capacity in any attempt of this sort to control a given epidemic.

Third, the actual technic in individual families would be a simple matter. We would collect about 25 c.c. of blood each from the father and from the mother for each child to be injected, and mix these two samples. Immediate centrifugation of this blood would yield about 25 c.c. of serum which would then be aspirated into a syringe and injected into the back muscles of the child. In an emergency, whole blood could be used instead of the serum, but twice as much volume would be required for a given quantity of antibodies injected and more foreign material would be injected in the way of blood cells and fibrin, and this material would provoke a much more lasting local reaction, with consequent pain and discomfort. One or more portable outfits of centrifuge, antiseptics, syringes, dressings, and the like should be provided the State Board of Health for immediate transportation to an afflicted area. The cost of such an outfit would probably not exceed $500.00 In the larger communities, much of this material would already be on hand in the hospitals, clinics, and their laboratories. It should here be explained that 25 c.c. of serum is accepted as a proper dose because that is the approximate dose commonly recommended for the treatment of a case of poliomyelitis that has actually begun. In drawing blood from father and mother, it has been shown above that in a certain percentage of the cases we would expect to have immune bodies in the blood of only one of the donors, and this would result in only half a dose. Objections to this cannot be completely answered, but there is no good measure of what constitutes proper dosage anyhow, so it may as well be agreed tentatively that a half dose is better than none.

If, then, these injections can be administered within a period of a few days to the greatest part of the child population, it can logically be hoped, though admittedly it cannot be expected before several trials, that the desired number of susceptibles in the community will have been passively immunized for a time interval longer than the incubation period of the disease, and that therefore the chances of the spread of the epidemic will have been tremendously reduced.

or the sake of clearness, it must be again emhasized that this method is aimed at a single pidemic; if the injections should happen to give at degree of passive immunity which would ermit individuals accidentally exposed during is period to go on to a stage of active immuity, the circumstance would be a happy, though rgely an unexpected, one. Indeed this brings p the main point of objection that can be raised gainst this proposal. That is, it might be argued at we are simply increasing the number of suseptibles to provide soil for a more serious sitation in a subsequent epidemic by tiding them ver a time in which many would otherwise deelop an active immunity. The answer is, of ourse, that there is nothing to prevent the repetion of the method as frequently as is necessary keep the disease in check.

No attempt is made to summarize this paper as e controversial points are fairly numerous, and n interested reader should examine, think about, nd decide on them individually. The writer beeves, however, that the suggestions here set orth are sufficiently sensible to warrant an actual ial in the field.

PRESIDENT'S LETTER

"There Is Nothing Sacred About the Ancient Practice of Private Service for Private Fees."

LAST month the Public Health Education Committee quoted the above in its Forum from a recent official report of the Social Service Conference in Minneapolis.

This pronouncement is an extremely interesting sidelight on the state of mind of the social worker, this new professional in the field of care for the unfortunate. He is full of fine theories, this new professional; of scientific smatterings; of doctrinaire opinion. He knows a little about medicine and is fired with a laudable ambition to force upon the public all he knows and, sometimes, a good deal that he doesn't know about public and private health.

He has encountered difficulties, of course. Old precedent; the indisposition of most men to be forcibly educated into enlightened disease prevention, unwanted medical care and sanitation; economic entanglements and the point blank refusal of the doctors themselves to be drawn into anything that seriously endangers "the ancient practice of private service for private fees"—in other words, the ancient unhampered confidential relation between the doctor and his patient.

It is natural, probably, that he should be impatient at obstacles, particularly impatient at these incomprehensible physicians who are not rejoiced to come out of the small domain of private practice and become officers of the state for imposing their knowledge and skill upon the public.

This public has never been very tractable when it came to imposing ideal procedures of any sort upon it by administrative or legislative act.

The working of prohibition is an adequate example of public rebellion at measures of this sort and with it political graft and organized lawlessness.

The establishment of state medicine, which would inevitably become compulsory state medicine, opens the way to comparable irregularities and misfortunes.

Already the keen eye of the political aggrandizer has seized upon the well meant propaganda of the social worker to his profit. Doubtful laws have been passed in a good many different states, and the charlatans, the quacks and the ism-practitioners are finding their second wind through them.

I am in great hopes that the Medical Economics Committee appointed at our last state meeting will be able to inform us very definitely on everything that relates in Minnesota to the knotty problem of medical costs. There is some better way to deal with the problem of care of the sick than to rush still further into governmental paternalism. But we cannot defend and preserve all that is sacred in "the ancient private practice of medicine" unless we are able to check from authoritative sources the facts and figures of the social worker.

L. Sogge

President
Minnesota State Medical Association.

Vol. XIV October, 1931 No. 10

POLIOMYELITIS IN MINNESOTA

This year, instead of the usual relative absence of poliomyelitis cases during the winter and spring months, there were following the epidemic of 1930 twenty-eight cases with six deaths during the first six months. During the last week in July case reports increased rapidly for a total of twenty-eight cases for the month. In August there were 165 cases, and up to September 5 eighteen cases had been reported. This situation calls for alertness on the part of the physician to recognize cases of poliomyelitis, and especially to attempt to make the diagnosis in the preparalytic stage, as the evidence of the beneficial effect of convalescent human serum in the treatment of these cases before paralysis occurs is increasing.

Fortunately the Division of Preventable Diseases of the State Department of Health started preparing convalescent serum in increasing amounts as soon as the situation began to cause uneasiness, and a reasonable amount of serum is still available. As long as the supply lasts serum can be secured promptly by communicating with the Division, preferably by telephoning through the University of Minnesota. Twenty to 30 c.c. is furnished and should be injected intramuscularly as soon as possible. If too much time will elapse through waiting for convalescent serum, whole blood injected intramuscularly is considered of distinct value, as experiments have indicated that in individuals over two years of age who have never had clinical poliomyelitis the blood has protective bodies against poliomyelitis in as high as 50 per cent of the cases. This percentage increases in adult years and is higher in the urban than rural populations.

Stress must be placed upon the use of the serum in the preparalytic stage, which places a great obligation on the physician not to overlook cases of true poliomyelitis and on the other hand not to waste the serum by giving it to patients not suffering from this disease and thus deplete the supply before the need for it has passed.

In the presence of an acute febrile state, especially in a child, if there is evidence of stiffness of the neck, and more especially if there is stiffness and pain in the spine as indicated by having the patient attempt to bend in order to touch his knees to his head, poliomyelitis is the most probable diagnosis. This diagnosis may be made positively if in addition the spinal fluid examination reveals a moderately increased pressure with an increase in cells sometimes as low as 20 or as high as 700 or 800 per cu. mm. These cells at first may be largely polymorphonuclear but later are lymphocytes. The fluid is clear but to transmitted light may have a somewhat "ground glass" appearance. A positive globulin test occurs. No organisms are found. A clear sensorium in the presence of these findings is helpful in making a differential diagnosis. In any febrile case that continues to be doubtful an early spinal fluid examination is justifiable, especially during an epidemic. If a minimal quantity of fluid is removed aseptically no possible harm can result and may be the means of instituting early treatment. This is not to be construed as a justification for indiscriminate spinal punctures in early febrile states.

Until some early positive diagnostic means becomes available the diagnosis in the abortive and non-paralyzed cases will remain difficult and often impossible, but attention to the above simple rules will be found of distinct value.

It is hoped that the present reduction of mortality and morbidity from the early use of convalescent human serum may continue and that the supply of serum will be entirely adequate for future needs. E. J. Engberg, M.D.

INCREASING CLIENTELE

We are confronted from time to time with propositions conceived by some individual with an eye to business purporting to increase our field of professional usefulness. Most of us have the laudable desire to increase our clientele but we occasionally have a way of jumping at some tempting bait without careful investigation.

A newspaper man conceives the idea that the local medical profession should receive more publicity and works up the idea of a Sunday supplement array of photographs with an accompanying write-up of the leading members of the local profession—for a consideration.

Or someone gets out a bulletin and to help defray expenses seeks permission over the telephone to include your name—at a nominal charge.

Or a persuasive individual shows you a copy of a directory of experts in the legal and medical profession which has been published for forty or fifty years. You glance it over and sure enough it contains a very select list of the outstanding men in your locality and elsewhere. You are secretly flattered. The cost is moderate. Perhaps something of this sort is just what you should take on. Your true worth is finally coming to be recognized. You sign on the dotted line, later to find that the publication has little organization and no one has ever heard of it.

Or some layman is getting up something new and different—a directory of reliable physicians all over the country. Only those free from commercial taint and recognized by the profession itself are to be included. Data given will be so complete that selection of a physician for reference of patients will be easy. How much demand for such a publication there will be, however, is a matter of speculation.

Whether a medical directory of the professional standing of physicians edited by a layman can possibly be as reliable as one published by a medical organization, is questionable. The American Medical Association has for years published a directory of all licensed physicians which contains useful and reliable information, although admittedly not as complete as might be desired.

A limited directory appears in a number of the state medical journals. Paid insertions resembling professional cards with name, specialty and address appear monthly in the advertising section. This practice falls into the category of local custom and cannot be criticized. We can see some convenience in the method, but most physicians are well acquainted with the profession of the state and state journals have as a rule a limited circulation outside of the state. We imagine few physicians would refer patients on the basis of state journal insertions. Incidentally the practice furnishes an added source of income to the state journal and might be considered by our Association.

These numerous efforts to furnish reliable information as to professional qualifications have more or less worthy motives. Most of them, however, are attempts at forcing the growth of medical practice.

To quote from the "Principles of Medical Practice" of our national association: "The most worthy and effective advertisement possible even for a young physician, and especially with his brother physicians, is the establishment of a well-merited reputation for professional ability and fidelity. This cannot be forced but must be the outcome of character and conduct."

The newspaper publicity mentioned is, after all, direct advertisement. Directory insertions, while not strictly unethical, are probably of little value as a means of increasing one's practice.

CORONARY THROMBOSIS

The practical importance of the recognition of coronary thrombosis lies in the need for prolonged rest following the attack. As far back as 1912 Herrick described the clinical symptoms due to coronary occlusion, but it was not until recent years that the diagnosis became common.

The picture once recognized, the diagnosis is not difficult. The ashen complexion, weak and rapid pulse which may be one characteristic of fibrillation, the low blood pressure, and the pain, cardiac in distribution, form a syndrome which often is unmistakable. The pain may be precordial or epigastric, and may be agonizing or simply a distress, and is of longer duration than that of a typical angina pectoris, lasting sometimes for hours instead of minutes and often requiring more than one hypodermic of morphine for control. Vomiting associated with the pain is not unusual and is likely to draw the attention of the attending physician to the digestive system. A moderate elevation of temperature and leukocyte count after twenty-four to thirty-six hours confirms the diagnosis. The development of a pericardial friction rub or a stroke some two or three weeks later clinches the clinical diagnosis.

The electrocardiogram is a refinement in diagnosis which, though not essential, is usually confirmatory, showing as it usually does a gross disturbance of the myocardium. The high take-off of the T wave from the down-stroke of the R wave or its low take-off from the up-stroke of the S wave are likely to be present in the acute stages. In later records an upwardly convex S-T interval and negative T waves are likely. The electrocardiogram may return to normal with convalescence.

As the accident follows a coronary sclerosis the history generally brings out significant data. The patient has had symptoms attributable to arteriosclerosis—perhaps typical attacks of angina pectoris, evidence of poor myocardial response, intermittent claudication, or he (usually it is he) is at that age at which arterial degeneration is to be expected. Instances below the age of forty are comparatively rare.

Rest over a period of six weeks or more is most important. Rest and sedatives are the most essential treatment. Digitalis is probably not indicated in the absence of congestive heart failure and in some instances may be actually harmful. In the presence of heart block barium chloride has been recommended.

It is surprising with the increasing frequency of diagnosis how many patients recover from an attack in spite of the necessarily severe damage to the heart muscle. Location of the infarct and the size of the thrombosed vessel have an important bearing on the final outcome.

Before the clinical picture of coronary thrombosis came to be recognized by the surgeon as well as the internist, patients not infrequently underwent laparotomies due to mistaken diagnoses. Many reported dying from acute indigestion doubtless have been the victims of coronary thrombosis. With the syndrome in mind the diagnosis is comparatively simple.

HIBBING AND THE NORTHERN MINNESOTA MEDICAL MEETING

More than eighty practitioners of Medicine registered at Hibbing and attended the fine day's session of the Northern Minnesota Medical Association. Despite the depression and oppression, the attendance from such a wide area was, as ever, a fine indication of most doctors' zeal for instruction and organization, and enjoyment in fraternizing with their fellows.

Hibbing has much of interest to show its guests and visitors: a noonday trip on flat cars through the enormous open pit mines was a thriller equal to a review of the Panama Canal, with which comparative figures of earth movement are so often made.

The selection of Dr. G. S. Wattam of Warren for president brought to a most distinguished pioneer a much merited honor, and to the society a pledge of continued farsighted leadership.

No one can see in such amplified sectional meetings, or what are virtually yearly assemblages of contiguous county society groups, any interference with the purposes or prerogatives of the State Association. It seems necessary at times to reiterate this opinion because the notion abounds that defections, through hospital staff meetings, special groups, or the great colleges, detract interest and support from the official groups leading up to the American Medical Association. This notion is not denied by those who neither attend hospital staff meetings nor like them; men who are supposed to remain away from state and American Medical Association meetings because they ingest medical pabulum to satiety at home. Go to all these meetings, and you will find the sturdy veterans in the benches at all the good meetings. To locate the rest, for present or future, is not the purpose of this editorial.

E. L. T.

« A PAGE FORUM OF THE COMMITTEE ON PUBLIC HEALTH EDUCATION »

Concerning the New Plan for Veterans Aid

The recently created Auxiliary to the Committee on Legislative Affairs occupied itself at a recent Chicago meeting with the so-called Shoulders Plan for disability insurance for veterans. This plan originated with H. H. Shoulders of Tennessee in the House of Delegates meeting held in June.

Following is a brief recapitulation of the Committee discussions, a complete report of which, together with recommendations for a campaign to promote the plan as a substitute for the present federal hospitalization plan, will be ready for publication shortly:

Veterans hospitals as now administered are full of veterans who have been completely and needlessly removed for long periods from their families.

Other equally deserving veterans have been totally unable to avail themselves of the medical service due them because they have refused to leave their families under such conditions.

Under the new plan for disability insurance there would be no need for the veteran to abandon his family in order to avail himself of his legitimate government aid. He would not even be obliged to leave his job unless his condition actually required hospitalization, in which case he could be hospitalized at an institution of his own choice near his own home.

At the present time there are some 220,000 empty beds in civilian hospitals in this country. The hospitals are inevitably handicapped, their efficiency reduced. Removal of veterans from their local communities is constituting an inceasingly serious problem to hospital administrations in their endeavor to maintain high standards of service at a price the general public can afford to pay.

Taxpayers are being unnecessarily taxed to pay for additional unnecessary beds in government hospitals while local institutions struggle with the problem of operating with 40 per cent of their beds vacant.

Doctors Pick 4-H Club Winners

On Tuesday, September 8, the Public Health Education Committee coöperated with the University Farm School and the Minnesota Public Health Association in examining nearly 100 4-H Club contestants for the boys' and girls' health championships of Minnesota. Ten specialists, under the direction of E. A. Meyerding, Executive Secretary, examined and graded the contestants at the 11 West Summit Avenue headquarters of the Minnesota State Medical and the Minnesota Public Health Associations. They reported, among all of these farm boys and girls, a remarkably high level of physical development. The finest specimens of all, however, and the highest score sheets, appeared wherever the medical profession had participated in the preliminary county contests. The winners were Geraldine Kohler of Windom and Clint Peterson of Worthington. Bernice Olson of Fulda, second highest among the girls, will go to Chicago with Clint Peterson in December to represent Minnesota in the national contest, because Geraldine Kohler is only thirteen years old and a year too young to be eligible for the trip.

As a rule the girls showed better physical condition, better posture and better grooming than the boys according to the examining experts. Such hunched shoulders and hollow chests as appeared among them were thought to have been caused by tight brassieres worn to achieve the flat figure which, until recently, led the styles.

It was worthy of note that the bunions, calluses and small calves usually noted among young people of this age were almost entirely absent. The ages of the girls examined ranged from thirteen to twenty, the boys from twelve to eighteen.

OF GENERAL INTEREST

Dr. C. M. Adkins has moved from Grygla, Minnesota, to Thief River Falls, Minnesota.

Dr. V. J. Telford, formerly of Edgerton, Minnesota, is now located at Litchfield, Minnesota.

The next meeting of the Association of Resident and Ex-Resident Physicians of The Mayo Clinic and The Mayo Foundation will be held October 8, 9 and 10.

Dr. A. A. C. Nickel, formerly of the Mayo Clinic, Rochester, Minnesota, has moved to Bluffton, Indiana, and is associated with the Caylor and Nickel Clinic there.

Dr. W. H. von Lackum, for the past eight years associated with the Section on Urology of the Mayo Clinic, has recently left Rochester. He has located in New York City, where he has entered training in preparation for the practice of orthopedic surgery. His address is 135 Slocum Crescent, Forest Hills, Long Island.

Dr. Ira M. Roadman, who has been in the Indian Service at Ponsford, Minnesota, for the past twelve years, is retiring from the Service to engage in general practice. Dr. Roadman's stay at Ponsford is considered a record for length of service of any physician at one station in the Indian Service. He has moved to Minneapolis where he expects to open an office soon.

Dr. Fred J. Pratt of Minneapolis attended the meeting of the American Academy of Ophthalmology and Otolaryngology, held at French Lick Springs, where he taught at the Section of Instruction, which was held in conjunction with the meeting.

Dr. John A. Pratt also attended the American Academy meeting, where he gave a paper on "Atrophic Rhinitis."

The Polk County Medical Society sponsored a joint meeting of the Friendly Valley County Medical Societies, at the Osceola Hotel, Osceola, Wisconsin, on September 23, 1931.

The periodic health examination was the subject of discussion and an actual examination illustrated it. Among the speakers were: R. G. Leland, Director, Bureau of Economics, American Medical Association, Chicago; W. A. O'Brien, Pathologist, University of Minnesota, Minneapolis, and C. B. Wright, Minnesota Delegate to the American Medical Association, Minneapolis.

A six o'clock dinner was served.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

SAINT PAUL QUACK PLEADS GUILTY TO VIOLATING BASIC SCIENCE LAW

State of Minnesota *vs.* Lobac

Charles Lobac, thirty-seven years of age, who claims to be a barber from Fresno, California, entered a plea of guilty to violating the Basic Science Law in the District Court at St. Paul before the Honorable Gustavus Loevinger, Judge, August 6, 1931. The defendant was arrested at Sixth and Wabasha Streets in St. Paul, where he plied his trade of selling a preparation called "Radian." The charge was one dollar per bottle, and the compound was alleged to cure everything from cancer to loose teeth. After spending six days in the county jail, the defendant heard the call of the harvest fields, entered a plea of guilty and was sentenced to thirty days in the St. Paul workhouse. The sentence was suspended after the defendant made an earnest plea to the Court that he be given a chance to leave the state and work in the harvest fields.

Mr. Brist reports that the State Board of Medical Examiners received very splendid coöperation from Detectives Tuckner and Johnson attached to the office of Michael F. Kinkead, county attorney, as well as from the county attorney's staff. Judge Loevinger very firmly informed the defendant that the practice of healing was intrusted to only those well educated and trained in that direction. No further trouble should be had with this defendant.

SECOND OFFENDER RECEIVES ONE YEAR IN WORKHOUSE

State of Minnesota *vs.* Ebeling

The above defendant, E. F. C. Ebeling, sixty-five years of age, who on June 10, 1931, entered pleas of guilty to violating the Basic Science Law and the Statute against distributing circulars and pamphlets on the restoration of lost manhood and other ailments, was committed to the Minneapolis Workhouse for a period of one year on September 8, by the Hon. Mathias Baldwin, Judge of the District Court.

Ebeling paid a fine of $100 in June for violating the Basic Science Law and received a suspended sentence of one year in the Workhouse for distributing the pamphlets. On August 23, Ebeling inserted an advertisement in the Minneapolis Tribune informing the public that he had the "new and right way to help Rheumatism, Stomach, Bronchial Asthma, Hay Fever, etc." He was arrested the next day on a complaint filed by Mr. Brist, representing the State Board of Medical Examiners, with the foregoing result. This means that Ebeling will spend the next twelve months in the Workhouse and undoubtedly it will "cure" the defendant of any desire to practice healing without a license, which should also serve as a warning to others similarly situated.

A very splendid attitude was shown in this case by Mr. Howard R. Hush, Chief Probation Officer, Hennepin County, and Mr. Archie Helwig, Deputy Probation Officer. Judge Baldwin is also to be commended for the prompt revocation of the suspended sentence. This indicates very clearly that quacks are going to receive some stiff jail sentences for repeated violations of the Medical Laws of this State.

ITINERANT PHYSICIAN SENTENCED TO SIX MONTHS IN COUNTY JAIL

State of Minnesota *vs.* John Edmund Doran

On Friday, August 21, 1931, the above defendant, John Edmund Doran, fifty-nine years of age, a licensed physician in the State of Minnesota, entered a plea of guilty to practicing medicine as an itinerant physician without a license before the Honorable Julius E. Haycraft, Judge of the District Court at Albert Lea, Minnesota.

For the past several years Dr. Doran has made a practice of traveling about the State of Minnesota and maintaining an office temporarily in hotels where he received patients after having advertised in the local newspapers his contemplated visit to the community. Among the towns where Dr. Doran maintained an office are Mankato, Winona, St. Cloud, Canby and Albert Lea. Dr. Doran was arrested on August 11, on a complaint filed by Mr. Brist, representing the State Board of Medical Examiners. The defendant waived his hearing and was held to the District Court under $1,000 bail. Dr. Doran finally decided to plead guilty with the foregoing sentence. Judge Haycraft suspended the sentence upon several conditions, the important one being that Dr. Doran is to refrain absolutely from practicing medicine in this state in more than one town. Dr. Doran is registered with the Board as maintaining an office at 335 Boston Block, Minneapolis.

OBITUARY

Henry J. O'Brien

1862-1931

Dr. Henry O'Brien, for years one of the leading surgeons in Saint Paul, died at his home September 16, 1931, following a stroke.

Born in Bayfield, Wisconsin, April 21, 1862, the son of Mr. and Mrs. Dillon O'Brien, he was brought to Saint Paul as a child, where he attended the public and parochial schools. The youngest in the family of one of the early settlers in the Madeline Island region, Dr. O'Brien returned for vacations frequently to his summer home on the island.

After receiving his medical degree from the University of Pennsylvania in 1888, he served as the second interne at St. Joseph's Hospital, Saint Paul, the first interne having been the late Dr. Arthur J. Gillette.

As a young man he became associated with Dr. Charles E. Smith and Dr. Everton J. Abbott. As years went on he showed his kindly interest in others of his profession by sharing his office and experience with a number of younger surgeons. Many a younger member of the profession could tell of instances of his generosity, which was one of his outstanding qualities. One of the first in Saint Paul to specialize in surgery, Dr. O'Brien enjoyed a well merited and extensive practice.

Early in his professional career Dr. O'Brien married Miss Mary King of Saint Paul. Three years after her death in 1909, he married Miss Caroline M. Beaumont, who survives him. He is also survived by two sons, Wallace D. O'Brien and Everton J. D. O'Brien, both of Saint Paul; one brother, Honorable Thomas D. O'Brien; two sisters, Miss Mary O'Brien and Mrs. Stan Donnelly, Sr.; and two grandchildren.

Dr. O'Brien was a member of the Ramsey County Medical Society, the Minnesota State Medical Association and the Minnesota Academy of Medicine.

W. L. Klein

Mr. William Livingston Klein, publisher of *The Journal Lancet* for over forty years and a resident of Minneapolis since 1881, died at his home August 20, 1931.

Borne in Barry, Illinois, on January 28, 1851, he attended Phillips Academy and Cornell University. After graduation from college he became head of the Normal School at Avon, New York, and while there, was married to Nora C. Sprague, daughter of a Syracuse judge. After being principal of a school in Woodstock, Illinois, he founded a book publishing company in Chicago, which still carries his name.

Moving to Minneapolis in 1881, partly on account of Mrs. Klein's health, he became the publisher of *The Journal Lancet* (then known as the *Northwestern Lancet*) in December, 1887. Two years before his death, on account of ill health, he sold the publication to the Cohen brothers.

Although known as a publisher, he was an able editor in addition. The tone of his publication attests the fact. His keen analytical mind is shown by his book entitled "Why We Punctuate or Reason Versus Rule in the Use of Marks," the second edition of which appeared in 1916, the first edition having appeared in 1896.

Mr. and Mrs. Klein were among the founders of the Trinity Baptist Church in Minneapolis and were very active in its progress. Mr. Klein is survived by his wife and two sons, Kenneth O. Klein of Minneapolis, and Horace C. Klein, president of the Webb Publishing Company of Saint Paul.

ARSPHENAMINE AND NEOARSPHENAMINE

Comparisons of the therapeutic value of arsphenamine and neoarsphenamine must take into account the difference of arsenical content, which is one-third higher in the case of arsphenamine than in the case of neoarsphenamine. Even allowing for this difference, it is quite generally conceded that arsphenamine as such is therapeutically the more effective than neoarsphenamine. The evidence for the efficiency of neoarsphenamine is conspicuously small. The most carefully investigated and reported clinical material has been treated with arsphenamine rather than with neoarsphenamine. One of the characteristics of neoarsphenamine, which will affect any attempt to estimate its gross clinical value, is the marked variability between different lots of the preparation, even from the same manufacturer. (Jour. A. M. A., August 15, 1931, p. 480.)

CONSULTATION BUREAU

WM. A. O'BRIEN, M.D., *Director*

Minnesota State Medical Association
11 West Summit Avenue
Saint Paul, Minnesota

1. *Question*—Please send me information concerning poliomyelitis. I am particularly interested in the use of convalescent serum, where it may be obtained, how much to give, and its probable effect.

Answer—Acute anterior poliomyelitis is a pathological misnomer to a certain extent. The usual after-effects represent chiefly the involvement of the anterior horn cells. The pathologists see an entirely different lesion at necropsy. There is involvement of the anterior horn cells, diffuse and focal myelitis and usually meningitis and encephalitis. Many of the fatal cases show bulbar lesions but death is more frequently due to paralysis of the cervical and thoracic regions.

The term infantile paralysis also fails to accurately state the case as the disease is rare in true infancy. The disease usually occurs in the young but may be found at any age. The peak of incidence is usually in the fall and frequently subsides with the coming of cold weather. There are also exceptions to this rule as the disease may persist well into the fall and may occur at any time of the year. The outbreak in the fall is frequently associated in many minds with the opening of school. This is probably not true.

The disease occurs in both the paralytic and non-paralytic forms and most observers believe it is due to a virus. When the virus of poliomyelitis is mixed with pooled serum from the general population, it is found to be approximately 80% efficient in protecting monkeys from cerebral inoculations. This seems to indicate that a large percentage of adults have had the non-paralytic form of the disease at some time in the past. At the same time the paralytic poliomyelitis is present, there are numerous cases of ill-defined maladies in the community. These are usually interpreted as non-paralytic forms of the infection in the light of our present knowledge.

The pre-paralytic symptomatology is not characteristic. It may mimic any one of several minor forms of general disturbance. Fever is usually present. The patient may have a sore throat, gastro-intestinal upset, malaise, general muscular soreness, spinal rigidty, headache, neck rigidity, positive Kernig's sign, or other complaints. Convalescent serum is most effective when given in the pre-paralytic stage. It may be obtained by getting in touch with the Division of Preventable Diseases of the State Board of Health in Minneapolis.

Anti-bodies apparently persist after infection. It does not seem to make very much difference how much time has elapsed since the donor had the disease. The serum is usually pooled but individual donors may be used and approximately 20 to 30 c.c. are injected intramuscularly into the buttocks. Its value is very difficult to ascertain because of the difficulty in making a diagnosis before paralysis develops and because the paralysis shows spontaneous tendency to improve. It should be used in selected cases with these reservations.

In some epidemics, epidemiologists insist on an increased spinal fluid cell count before it is given. While meningeal involvement is usually present, it may be absent or mild in degree. When paralysis of the muscles of respiration develop, the Drinker apparatus is used for the purpose of augmenting the patient's own efforts at respiration. It is not in any sense a curative measure but simply acts as a mechanical aid. If the disease does not progress, it is most helpful in maintaining life. Paralysis is seldom the initial symptom and is usually preceded by an illness of varying time and severity. All patients with swallowing difficulties should be considered suspect poliomyelitis cases until proved otherwise. In case of doubt, physicians should communicate with the Division of Preventable Diseases for advice and assistance. All patients who have recovered from poliomyelitis should be encouraged to offer their blood for the collection of convalescent serum. Paralytic cases should have the affected parts placed in some type of corrective device to prevent deformity. Whether motion should be started early or late is still a matter of conjecture and well-informed men will be found on both sides of the question.

2. *Question*—I recently purchased a Sahli hemoplobinometer. The circular which accompanied it stated that 100% represented a different amount of hemoglobin than I was accustomed to use in terms of grams in each 100 c.c. How is it possible to convert this figure?

Answer—It is usually best to standardize each tube and to disregard the manufacturer's statement as to the amount represented on the scale. This may be done by accurately counting the blood of five or ten persons with an average of 5,000,000 cells per cubic millimeter. The average hemoglobin reading of the group should be taken as 100% and the correction used for all the figures.

3. *Question*—What is the latest treatment for the correction of so-called "trench foot" in the army?

Answer—I assume you mean by "trench foot" the condition also known as "athelete's foot" or "epidermophytosis." If the lesions are acute or weeping the best treatment is a pack of 1-4,000 solution of potassium permanganate, and bed rest. When the condition is under control, it may be treated as a chronic affair. The best treatment at this stage is Whitfield's ointment, half or full strength, applied twice daily. Full strength of Whitfield's ointment is salicylic acid 2, benzoic acid 4, and petrolatum 30 (metric).

It is rather difficult to predict the outcome as re-infection is difficult to avoid. If the patient can boil his socks, change his shoes frequently, and avoid stepping on affected floors, *e.g.*, swimming pools and gymnasium, a cure is possible. It is a difficult persistent disease to treat and many things have been tried. Some of these remedies advertised directly to the laity are not a cure-all. Many articles have recently appeared concerning this disease and if the above treatment is not effective, please write again.

COMMUNICATION

Terre Haute, Indiana
June 20, 1931

Dear Sirs: Re: Goiter Classification and Nomenclature.

This association would appreciate very much your giving wide publicity to its approval of the following classification and nomenclature:

Clinical Classification:

Type 1—Non-toxic Diffuse Goiter
Type 2—Toxic Diffuse Goiter
Type 3—Non-toxic Nodular Goiter
Type 4—Toxic Nodular Goiter

Nomenclature:

Our association advocates a policy of using the simplest and yet the most descriptive terminology possible.

The use of proper names, while it is impossible to dispense with many well established ones in goiter literature, be discouraged; as should coined words invented to popularize a fad or fancy.

Emphasis should be made upon the importance of not confounding varieties and sequelæ with types. The use of such terms as exophthalmic, hemorrhagic, cystic, adolescent, colloid, intra-thoracic, substernal and congenital are perfectly proper when used to describe varieties, but only constant characteristics should be used to designate types.

Thanking you very much for your cordial coöperation, I am,

Fraternally yours,
American Association for the Study of Goiter,
J. R. Young, M.D., *Corresponding Secretary.*

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

MEDICAL BROADCAST FOR THE MONTH

The Minnesota State Medical Association Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 11:15 o'clock every Wednesday morning over Station WCCO, Minneapolis and Saint Paul (810 kilocycles or 370.2 meters).

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota.

The program for the month of October will be as follows:

October 7—Corneal Ulcer
October 14—Prevention of Hay Fever
October 21—Cretinism
October 28—Brain Tumor

MINNESOTA MEDICAL ALUMNI ASSOCIATION HOMECOMING PROGRAM

The homecoming football game will be the occasion for the return of many medical alumni to Minneapolis. The committee of the Medical Alumni Association is again making it possible for the returning alumni to enjoy a worthwhile scientific program in connection with their visit.

At 9 A. M., Friday, October 30, 1931, the day preceding the game, the following program will be presented at the Eustis Amphitheatre in the University Hospital:

Dr. J. F. Corbett, Minneapolis, presiding

Oral Cholecystography—J. R. Aurelius, St. Paul
Pediatric Clinic—Irvine McQuarrie, Head of Department of Pediatrics, Medical School, University of Minnesota
Skin Lesions (demonstration by lantern slides)—John Butler, Minneapolis
The Present Status of Surgery of the Gall Bladder—E. Starr Judd, Rochester, Minn., President, American Medical Association.
Blood Pressure in Relation to Insurance Examinations—C. Naumann McCloud, St. Paul Medical Director Minnesota Mutual Life Insurance Co.
Practical Demonstration of Varicose Vein Injection—J. M. Hayes, Minneapolis.

Luncheon at 12:00 o'clock, at which time Dr. Richard E. Scammon, Dean of Medical Sciences, University of Minnesota, will speak.

The delegates will meet for the annual business meeting of the association at this time.

Dr. C. N. Hensel, St. Paul, will preside at the afternoon session, which will convene promptly after lunch and the business meeting, with the following presentations:

Orthopedic Clinic—Wallace H. Cole, St. Paul
Pain in Gynecological Diagnosis—S. B. Solhaug, Minneapolis
The Unimportant Heart Murmur—S. Marx White, Minneapolis, President, American College of Physicians.
Thoracic Surgery in the Treatment of Tuberculosis—T. J. Kinsella, Glen Lake Sanatorium.
Neurological Gaits and Other Conditions (demonstration with moving pictures)—J. G. McKinley, Professor of Nervous and Mental Diseases, Medical School, University of Minnesota

RED RIVER VALLEY SOCIETY

The Red River Valley Medical Society will meet at Thief River Falls, Tuesday, October 6. Speakers scheduled are: W. A. Fansler, Minneapolis; E. A. Meyerding, St. Paul; J. A. Myers, Minneapolis, and Mrs. S. S. Hesselgrave, St. Paul, who will address the Auxiliary.

Dr. Myers' subject will be "Tuberculosis." Dr. Fansler will talk on "Rectal Difficulties." Dr. Myers will also address a luncheon meeting at Thief River Falls on the same day.

DODGE COUNTY SOCIETY

The Mantoux tuberculin test will be discussed at a meeting of the Dodge County Medical Society to be held at Kasson on Friday evening, October 9, in the office of F. D. Smith.

Dr. J. A. Myers, Minneapolis, and Dr. E. A. Meyerding, St. Paul, will talk.

SOUTHERN MINNESOTA MEDICAL ASSOCIATION

Dr. Charles C. Allen of Austin was chosen president of the Southern Minnesota Medical Association at the annual convention held at Faribault, Minn., August 25.

Others elected are Dr. R. V. Williams, Rushford, first vice president; Dr. B. J. Gallagher, Wascca, second vice president, and Dr. M. C. Piper, Rochester, secretary-treasurer.

Medals were presented to Dr. W. P. Herbst of Minneapolis and Dr. R. K. Ghormley and Associates of Rochester for the best individual scientific exhibits at the State Meeting this year, and to Mr. T. C. Erickson, a senior medical student at the University of Minnesota, who in his junior and senior years was selected as having shown the highest degree of efficiency in the clinical fields of medicine and surgery.

JOINT MEETING OF CHISAGO-PINE AND CENTRAL MINNESOTA DISTRICT SOCIETIES

The question of amalgamation was discussed by the Chisago-Pine and the Central Minnesota District Medical Societies at Cambridge, on Thursday, September 17. Visiting speakers were: E. A. Meyerding, St. Paul; W. A. Coventry, Duluth; F. J. Savage, St. Paul, and Mrs. S. S. Hesselgrave, St. Paul.

D. E. McBroom, Cambridge, Superintendent, State Colony for Epileptics, acted as host for the meeting which was held at the Cambridge institution.

NORTH CENTRAL BRANCH OF THE AMERICAN UROLOGICAL ASSOCIATION

The eighth annual meeting of the North Central Branch, American Urological Association, will be held in St. Paul, Thursday, Friday and Saturday, October 29, 30, and 31, 1931.

Headquarters will be at the Lowry Hotel. The papers of the scientific program will be presented in the Ramsey County Medical Society assembly room, Thursday forenoon and afternoon, October 29, and Friday afternoon, October 30.

One afternoon session will be devoted to "Obstruction of the Upper Urinary Tract," for which Dr. Frank Hinman, San Francisco, will make an introductory address. The other afternoon session will be on "The Myoneural Mechanism of the Urinary Tract," for which Drs. James Learmonth and William F. Braasch, Rochester, will make introductory addresses.

Members of the Ramsey County Medical Society are cordially invited to attend.

Clinical demonstrations and urologic operations will occupy Friday forenoon at the Ancker Hospital, Saint Paul, and Saturday forenoon at the University Hospital, Minneapolis, and Glen Lake Sanatorium.

Dr. Frederic E. B. Foley, secretary, 229 Lowry Medical Arts Building, St. Paul, is in charge of arrangements.

WOMEN'S AUXILIARY

Minnesota State Medical Association

President—Mrs. James Blake, Hopkins
Chairman Press and Publicity—Mrs. Glen R. Matchan, Minneapolis
Editor—Mrs. Horatio B. Sweetser, Jr., Minneapolis

RAMSEY COUNTY AUXILIARY

The Ramsey County Auxiliary acted as hostesses to the visiting women attending the Mississippi Valley Tuberculosis Conference, September 21, 22, and 23. They had charge of a Registration Desk and held a tea, Tuesday, September 22, in the new Club Rooms of the Ramsey County Medical Society. A drive and golf were scheduled for the visitors. Women from eleven states attended the meetings. Mrs. W. H. Hengstler, as President of the Auxiliary, was assisted by the Hospitality Committee, Mrs. Edward Schons, Chairman, in the entertainment of visitors.

HENNEPIN COUNTY AUXILIARY

The Hennepin County Auxiliary opened their fall program with a talk by Dr. C. E. Rudolph on "The Cost of Medical Care," September 23, in the Club Rooms of the Hennepin County Medical Society.

The Hennepin County Auxiliary will take over the serving of luncheons again this fall, beginning with the October meeting of the doctors. Mrs. Stephen Baxter will be the general manager.

The Hennepin County year book just published promises an interesting program for the year. In October a Reciprocity Meeting will be held with two auxiliary artists presenting the program. Mrs. W. E. Patterson will read "The Flattering Word," a one act play by George Kelley, and Mrs. Harold Boquist will entertain the audience with musical numbers. Dr. Mabel Ulrich will talk on "Books" at the November meeting, and Mrs. E. G. Wanous will give one of her interesting book reviews at the Christmas Silver Tea. In January, the Auxiliary members are to have a "Great Day," when Mrs. Walter J. Marcley will talk about the Disarmament Conference.

SCOTT-CARVER COUNTY AUXILIARY

Scott-Carver Auxiliary will have a dinner meeting at the home of the president, Mrs. Simmons, in Chaska, Tuesday evening, September 8. A health movie program, with a health talk, will be the evening's entertainment. The doctors will meet the same evening for their regular business.

NEW AND NON-OFFICIAL REMEDIES

The following products have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in New and Non-official Remedies:

Sandoz Chemical Works, Inc.
Gynergen Solution 0.1 per cent

E. R. Squibb & Sons
Squibb Chocolate Vitavose

Winthrop Chemical Co., Inc.
Skiodan

Elixir No. 229 Ephedrine Sulphate 2 grains.—It contains ephedrine sulphate-Lilly (New and Non-official Remedies, 1931, p. 177), 0.44 Gm. in 100 c.c. (2 grains per fluidounce) in a menstruum composed of alcohol, glycerin, sucrose and water, with flavoring agents. Eli Lilly & Co., Indianapolis.

Ventriculin, 100 Gm.—Each bottle contains 100 Gm. of ventriculin (New and Non-official Remedies, 1931, p. 238). Parke, Davis & Co., Detroit. (Jour. A. M. A., August 8, 1931, p. 391.)

FOODS

The following products have been accepted by the Committee on Foods of the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in Accepted Foods:

Kellogg's Rice Krispies (Kellogg Co., Battle Creek, Mich.).—A ready to eat, cooked and toasted rice cereal flavored with malt syrup, sugar and salt. It is claimed to be a delicious, cooked, easily digested cereal.

Embo (Purified Wheat Embryo or Germ) (General Mills, Inc., Minneapolis).—Wheat embryo or germ practically free of bran or other parts of the wheat berry hermetically sealed in cans. It is claimed that the product retains the food value and vitamin content of natural wheat germ or embryo which is not modified in manufacture by any heating, bleaching or other process. Unless otherwise prescribed it can be conveniently ingested with minimum loss of vitamin potency by mixing with cereals, vegetables, fruits, after these have been cooked. (Jour. A. M. A., August 1, 1931, p. 321.)

Mazola (Corn Products Refining Company, New York City).—A canned refined corn oil. It is claimed to be a highly refined corn oil for baking and table uses.

Tea Table Sandwich Bread (Sliced) (Liberty Baking Company, Pittsburgh, Pa.).—A white bread made by the sponge dough method, in sliced loaf form. It is claimed to be a bread of good quality.

Liberty Delicious Bread (Liberty Baking Company, Pittsburgh, Pa.).—A white bread made by the sponge dough method. It is claimed to be a bread of good quality.

Liberty Grade A Bread (Liberty Baking Company, Pittsburgh, Pa.).—A white milk bread made by the sponge dough method. It is claimed to be a bread of good quality. (Jour. A. M. A., August 15, 1931, p. 463.)

PROGRESS

Abstracts to be submitted to Section Supervisors.

Members are urged to abstract valuable articles whic they run across in their reading and send the abstract to the physicians in charge of the respective sections. I order to avoid duplication it would be well to communicate with one of the section supervisors before th article is abstracted.

NEURO-OTOLOGICAL OBSERVATIONS IN CONCUSSION OF THE BRAIN: F. H. Linthicum and C. W. Rand (Arch. Otolaryngology. 13: June '31, p. 785). A series of thirty-six cases is reported in each of which some abnormality of the vestibular response was elicited. The authors refer to vertiga as being of two types:

1. A true or systematized vertigo in which external objects appear to revolve around the subject in a definite direction. This type is usually considered to originate in the end-organ and is often associated with spontaneous labyrinthine phenomena such as nystagmus, past-pointing, and characteristic disturbances in station.

2. False, or non-systematized vertigo, which may be simply a feeling of uncertaining or confusion. The lat-

ter form of equilibratory disturbance may be caused by ocular disturbances or intracranial lesions involving the vestibular tracts, or may be due to so-called neurasthenic vertigo. In other words, it does not originate in the end-organ, but may be the result of a derangement of the ocular, tactile, or joint muscle-sense or a combination of any of these.

The examination of the vestibular apparatus consisted of the turning tests and caloric mass irrigation. Independent neurological examinations had been made in most cases. The authors stress the importance of an accurate history, stating that it plays no small part in the final determination of the extent of injury and the consequent prognosis.

No definite statement is made of the actual number of these 36 cases in either group of the above mentioned classification. Only 6 persons failed to show some hearing impairment of the receptor or inner ear type manifested by the usual shortening of bone conduction and loss of acuity for high notes.

The authors conclude that in practically all cases of cerebral concussion, the patient complains of some form of equilibratory disturbance which may be demonstrated by some abnormality in neuro-otological observations. These observations are usually indicative of mixed central and end-organ damage rather than the involvement of the end-organ alone. The most constant observations are abnormalities in the past-pointing reactions. Traumatic equilibratory disturbances arising in the end-organ are more apt to readjust themselves than those of central origin.

Lawrence R. Boies.

THE CONTROL OF MYOPIA: Edward Jackson, M.D., D.Sc., F.A.C.S., Denver, Colorado (Amer. Jour. of Ophthal., Vol. 14, August, 1931, No. 8). The author starts this article with the statement that "Control of Myopia is practical, cure is not; and prevention is still in the future."

He then gives a review of the literature which in the past has for the most part been "theoretic and philosophic."

The author observes that excessive convergence without accommodation is the most important factor in progressive myopia, and that our most valuable therapeutic measure is the restoration, as early as possible, of the normal relation of these two functions. That myopia causes four per cent of the cases of blindness of both eyes and is liable to lead up to other causes, such as choroidal atrophy, detachment of the retina and cataract.

He then gives his observations taken from the examination of the records of all myopia in his private practice of over thirty years. Among patients under twenty-five years of age, when first seen, the time of life when myopia is most likely to develop and be progressive, were found seventy-seven cases, 154 eyes, which were examined after at least three years of wearing constantly their full correcting glasses.

These patients were under observation from three to thirty years, averaging the age of sixteen when first seen, and twenty-five at the date of last observation.

Of the 154 eyes there were twenty-seven that became less myopic. There were forty-four eyes that showed no change of refraction. There were fifty-two eyes in which the myopia increased less than 1 D. There were thirty-one in which it increased 1 D., or more, the average being 2 D. That is, under the constant wearing of full correcting glasses, 45 per cent of the eyes showed no increase of myopia at any time; 34 per cent showed an increase of less than 1 D., and only 21 per cent showed an increase of 1 D. or over, an average increase of nearly 2 D.

The enormous statistics showing the increase of myopia during school life and all careful observations of its course from Sir Charles Blagden in the 18th Century to the present day, indicate that the development and increase of myopia depend on convergence of the eyes for near work, and that avoidance of such convergence, by occupation and the use of concave lenses, is the foundation of its rational control.

For the common, most important form of axial myopia the program includes:

1. Avoidance of much use of the eyes for near seeing in early childhood, during the period of most rapid development and growth, up to six to ten years.
2. Testing the vision and examining the eyes of children entering school, especially for ocular defects that will lead to excessive convergence. Such testing should include accurate measurement of ametropia.
3. Watching the children in school to secure an erect posture and keeping of the book away from the eyes. Good print and good illumination both in school and in the home. Foerster showed that the home work done with the eyes was greater than the work in school.
4. Sight-saving classes for children having poor vision, or suffering from any ocular condition that would be seriously aggravated by ordinary school work. Each of these children should be placed in such a class on the advice of an oculist, who should see the child every three months, so long as the sight-saving supervision was necessary. In such a class the child should spend a part of the day in the special room for sight-saving instruction, and a part receiving oral instruction with seeing children of the same grade.
5. The constant wearing of accurate correcting glasses, especially of full strength concave glasses.
6. Regular daily, outdoor living and exercise; for children, youths and young adults.
7. Close attention to the child's general health and nutrition, including care as to vitamins, and endocrine secretions. As to hereditary and congenital myopia, this may need to be extended to the care of the expectant mother.

Such a program intelligently carried out would prevent most cases of myopia, would limit to low degree most of the cases that did arise, would prevent the degenerative changes that characterize the later stages of high myopia, and would prevent about four per cent of the blindness that now occurs in civilized countries.

L. G. Culver, M.D.

MEDICINE

TUBERCULOSIS ABSTRACTS*

Collapse therapy in tuberculosis is now an established procedure of unquestioned value. Clive Riviere said: "No more hopeful ray of sunshine has ever come to illumine the dark kingdoms of disease" than artificial pneumothorax. This therapeutic procedure, however, has its limitations. Mechanical difficulties brought on by the pathological condition of the lung often make collapse by the insufflation of air or gas impossible or ineffective. Latterly, the injection of oil into the pleural cavity for certain cases has found favor, especially among French phthisiologists. Somewhat timidly, oleothorax is being introduced and practiced in this country. From an article by L. E. Oppengame in the *American Review of Tuberculosis,* June, 1931, the following abstracts are derived.

OLEOTHORAX

Oleothorax is the injection of mineral or vegetable oil into the pleural cavity. The indications for its use are: to avoid adhesions, to produce a more effective collapse when pneumothorax is ineffective, to give more rigidity to the pleura if a bulging of the mediastinum occurs, to close a perforation of the lung, to change an empyema into a sterile disinfectant oil. In rare cases, it may be used instead of artificial pneumothorax when for any reason a patient cannot return for routine refills.

According to Fontaine's statistics, about 70 per cent of pneumothorax treatments are complicated by pleurisies, 22 per cent result in empyema, and 15 per cent make further collapse therapy impossible because of resulting adhesions. The reason pneumothorax continues to be used in the face of these troublesome sequelæ is because not all pleurisies are intoxicating for patients and a great number are beneficial for pulmonary tuberculosis. In fact, by some specialists, the development of pleural effusion is regarded as a natural healing phenomenon. There is evidence to show that pleural fluid has a deterrent influence on the development and the virulence of the tubercle bacillus. But certainly not all pleurisies are benign. Dumarest has classified pleurisies into the following groups:

Tolerated Pleurisies with little, torpid, precocious effusion produced by trauma or resulting from irritation of the pleural membranes from air insufflation. In these cases, there is no fever or pain, and reabsorption sometimes occurs by itself.

Acute Febrile Effusions (serofibrinous) which may appear any time during pneumothorax treatment but frequently between the third and fifth month. Effusions are profuse, there are chills, fever, a stitch in the affected side, dyspnea, irregularity of pulse, increased expectoration, and cough. The condition passes through phases but may persist for months. It is mostly benign, often regresses, and usually disappears when air refills are discontinued, but may subsequently cause adhesions. Empyema may, however, develop from it.

For these two forms of pleurisy, it is often better, after the acute stage is over, to aspirate the fluid and refill with air.

Malignant Pleurisies, or purulent, chronic effusions with high and prolonged fever, and causing malnutrition, may develop from the above mentioned forms. The difference is not easily recognized at once; only the evolution of the disease enables one to make the differentiation. Such malignant pleurisies result in complete prostration or amyloid degeneration and usually end fatally.

With rare exceptions, there is no use for oleothorax in benign pleurisies, but in malignant cases, the first step in any intervention should be an oleothorax. Even if the operation is unsuccessful, the patient is improved and thereby placed in a more favorable condition for further surgical interference, such as rib resection or thoracoplasty. For an empyema complicating an artificial pneumothorax (which means pleurisy with tuberculous lesions), oleothorax is the only choice as thoracotomy is almost always fatal. Thoracoplasty done for tuberculous pleurisies in general leaves a persistent fistula; oleothorax, if properly done, is entirely harmless. For secondarily infected pleurisies (streptococcic, pneumococcic), drainage and not oleothorax is the proper treatment.

OLEOTHORAX FOR LUNG PERFORATIONS

The use of oleothorax for lung perforations is very limited. A small perforation as the result of the breaking of adhesions or a rupture into the pleural cavity of a small, subcortical vomica not connected with a bronchus, justifies an oleothorax. Unfortunately, not very often are we able to differentiate the small, benign perforation from a large, fatal one. (The author describes differential signs.)

Temporary perforations do not need an oleothorax. Valvular perforations, not helped by deflation, are benefited by oleothorax. Large perforations are mostly fatal, but if unilateral and recognized at once, thoracoplasty is a help. Burnand and Roussel, however, injected oil in such cases, thereby disinfecting the pleura and placing the patient in better condition for a final thoracoplasty.

USE IN ADHESIONS

With oleothorax, adhesions may be avoided or prevented, though not all adhesions need an immediate oleothorax. (The beginning of adhesions can be foreseen by manometric readings and fluoroscopy.) In unsuccessful pneumothorax, for instance, in partial pneumothorax when only one part is collapsed far from a cavitation which remains open, air insufflations are not only useless but also dangerous because of the necessary high pressure.

OTHER INDICATIONS

Mediastinal hernia or bulging produced by low pressure on the opposite side of a pneumothorax may be reduced by oleothorax. Finally, in exceptional cases, if patients are not able to stay in the hospital or to return for refills, a pneumothorax may be changed into an oleothorax, which requires refills only about every two months.

---

*Reprinted from *Tuberculosis Abstracts,* a review for physicians, issued monthly by the National Tuberculosis Association, October, 1931, Vol. IV, Number 10.

TECHNIC AND RESULTS

Accidents have occurred from the injection of badly or anciently prepared, not-neutralized vegetable oil. But if all precautions are taken in its preparation, there is no great difference in the choice of the kind of oil used. The power of reabsorption depends more on the individual than on the kind of oil. The vegetable oil is milder for the pleura and not so irritant as mineral oil. The author uses mineral oil when he wishes to avoid thickening of the pleura and to produce more compression, while the vegetable oil is used mostly in empyemata.

For the last few years, he has treated many patients with oleothorax and has not had one death directly from the operation. Reported cases of death are probably due to neglect of the pressure which oil produces —a most important factor.

Of the four case histories cited by the author, the following is quoted:

Case 2: Miss A. B., age 21, admitted July 29, 1929. *Diagnosis:* Chronic pulmonary tuberculosis. *X-ray Report:* Bronchopneumonic type of pulmonary tuberculosis, mainly unilateral. *Left Lung:* Diffuse involvement of entire lung with multiple cavities in upper lobe. *Right Lung:* Negative, except for some hazy appearance at apex and increased size of hilar lymph nodes (?); lower bronchial roots somewhat prominent.

January 30, 1930: Initial pneumothorax 400 c.c.,-4, -1). *February 20, 1930:* After several refills, re-examination of the chest shows left-sided hydro-pneumothorax, with fluid level up to third interspace and displacement of mediastinum and trachea to the right. In the region of the left upper lobe is seen some lung tissue, with well defined and sharply demarcated area of lessened density which are undoubtedly uncollapsed vomicæ held by adhesions to the chest-wall.

February 24, 1930: Lemon-colored fluid aspirated from left chest (500 c.c.); 30 c.c. of oilgomenol injected; normal reaction. Patient had in four- to six-day intervals several injections until complete blockage was obtained by June 30, 1930. Since the last injection, we control the amount of oil once every four weeks. The reabsorption of oil in this case since a blockage was obtained was very slow, and we injected only 5 to 10 c.c. of oil once a month.

This case is particularly interesting. Why did we change an acute febrile effusion into an oleothorax and what effect was obtained by an oleothorax) Because in spite of the effusion, the cavitations in the upper lobe were open on account of adhesions and because a menacing mediastinal hernia (bulging) occurred which interfered with the further pneumothorax insufflation. After 2 to 3 months of oil treatments, we obtained a rigidity of the mediastinal pleura, the hernia disappeared, and we were able to inject a considerable amount of oil without fear of rupture. In the meantime, the patient developed after a pneumonia a right-sided pulmonary lesion. We feared to perform a right-sided pneumothorax on account of the left-sided oleothorax, and decided to inject sanocrysin intravenously. The patient is now in a very good condition.—*Aleothorax, L. E. Oppengame, Amer. Rev. of Tuberc., June, 1931.*

PEDIATRICS

STUDIES ON THE INCIDENCE OF TUBERCULOUS INFECTION: Elizabeth Leggett and F. F. Callahan (Amer. Rev. Tuberc., XXIV:2:113-135. August, 1931). The authors report a recent study on the incidence of tuberculous infection in several different groups of Minnesota school children. Results are compared graphically with those of similar studies elsewhere, and are shown to be lower in this series than those in larger cities as Vienna, Philadelphia and Minneapolis, but higher than for rural Minnesota or rural Hennepin county. Two different groups in Saint Paul were tested, the total number being about 600. The one group came from middle-class homes where known exposure was low. Of these, 20 per cent showed a positive Mantoux, and 6 per cent had X-ray findings of tuberculosis. The second group came from poor homes but here also the history of exposure was low. Of these, 22 per cent had a positive Mantoux; 7 per sent had X-ray findings. These figures are compared with the incidence in Minneapolis school children of 47 per cent as reported by Myers and Harrington. In the Pine City schools, 265 children were tested. Under 12 years, only 4 per cent were found positive as against 25 per cent in the high school group. The high incidence in the older children was explained by definite exposure to an active case of tuberculosis in a teacher. Work on a fourth group in Morrison county, where the incidence of the disease is known to be high, will be reported later. Of 274 children already examined, 31 per cent reacted positively. In both the Pine City and Morrison County groups, cases of active adult tuberculosis were found, while there were none in the St. Paul children studied. A limited study of autopsy material is added.

The authors stress the value of tuberculosis surveys in schools and emphasize the fact that a teacher with active pulmonary tuberculosis is a definite source of infection to children.

L. G. FRARY, M.D.

THE EFFECT OF PASTEURIZATION UPON THE VITAMIN C CONTENT OF MILK IN THE PRESENCE OF CERTAIN METALS: E. W. Schwartze, F. J. Murphy and G. J. Cox (Jour. Nutrition, 4:211, July, 1931). The Vitamin C destruction in fresh milk samples pasteurized aërobically in aluminium, tinned copper, and copper was determined quantitatively by measuring their values in preventing scurvy in guinea pigs. The destruction was placed at 20 to 40 per cent in aluminum. This is greater than that obtained upon boiling milk for 5 minutes, and is rather to be expected as the duration of exposure in pasteurizing is much longer and is strictly aërobic. The effect of pasteurizing milk in tinned copper was slightly greater than that found in aluminum, referable the authors believe to the small amount of copper exposed to the milk when in the tinned copper pasteurizer.

The pasteurization of milk in naked copper resulted in a destruction of at least 80 to 90 per cent of the antiscorbutic vitamin. Since less than 20 to 40 per cent of the loss must be charged to the aërobic pasteurization process itself, a greater portion of the loss must be attributed to copper.

The practical importance of these experiments is that copper is shown to be unsuited for construction in dairy equipment so far as the conservation of Vitamin C is concerned. Tinned copper is likewise unsatisfactory, but no difference was found between pyrex glass and aluminum. Aluminum, therefore, is as satisfactory a material as we have for construction of dairy equipment so far as the destruction to Vitamin C is concerned.

C. A. Stewart, M.D.

PHENYLETHYLHYDANTOIN: ITS USE IN CHOREA: S. W. Marick, M.D., Pittsburgh (Arch. of Ped., Vol. XLVIII, No. 8, August, 1931). Neither the dosage nor the modus operandi of phenylethylhydantoin is entirely agreed upon. It is generally administered until fever and a rash are produced. Most writers state that the result of administering phenylethylhydantoin in chorea is not due to the sedative effect of this drug, but to a specific reaction akin to "serum sickness." Most German writers stress the importance of the fever and rash. In the author's experience neither was a constant factor and improvement followed where both were absent. In fact, they failed to develop a reaction in about one-third of the cases, including some that improved promptly. They are of the opinion that it takes a certain concentration of the drug in the system to produce the toxic rash and fever, and that reaction is no way specific. The drug was not continued beyond two weeks.

Phenylethylhydantoin is administered for general purposes in doses of 0.2 gm. to 0.5 gm. although Bressler advocates doses up to 1 gm. in the more serious diseases of the nervous system. A large dose is generally given once a day.

Usually, between the eighth and fourteenth day, fever and a morbilliform rash appear, first on the wrists, then on the chest, abdomen and limbs. Fever and rash last four or five days and then disappear. As the rash and fever subside, improvement is noticed.

In most of the cases, definite improvement was noticed about one week after the conclusion of the course of treatment.

Over a score of cases of chorea were treated with phenylethylhydantoin. Most of these cases were mild or moderately severe. The results, as a whole, were good.

R. N. Andrews, M.D.

LOSS OF IMMUNE SUBSTANCES FROM THE BODY. II. DIPHTHERIA ANTITOXIN IN HUMAN SALIVA: J. K. Sugg and J. N. Neill (Jour. of Immunol., 20:463, June, 1931). Sugg and Neill report the presence of diphtheria antitoxin in the salivas of "naturally" immune persons and of one toxoid immunized person, demonstrated by the toxin neutralizing properties of the saliva of such individuals. They feel that the toxin neutralization by the immune salivas was due to true antitoxin and not to inactivation or destruction of the toxin by some non-immunological constituent of normal saliva. The action of salivary enzymes was ruled out by control tests with unheated salivas of non-immune persons, and the antitoxin was demonstrated by intravenous injection of guinea pigs with the saliva prior to subcutaneous or intradermal injections of the toxin. The daily output of salivary antitoxin was estimated as equivalent to about 0.07 per cent of the total amount of antitoxin in the circulating blood, at which rate a person would swallow during a year an amount of antitoxin equivalent to approximately 25 per cent of the amount originally present in his blood. Examination of stool extracts failed to detect any traces of the swallowed antitoxin, thus it was either destroyed or absorbed in the intestinal tract. The concentration of antitoxin in the saliva of immune individuals was found to bear a rather direct relation to its concentration in the blood.

C. A. Stewart, M.D.

COD LIVER OIL EMULSIFIED IN AN EXTRACT OF GERMINATING GRAINS: ITS TOLERANCE BY THE INFANT GASTRO-INTESTINAL TRACT AND ITS PROPHYLACTIC VALUE: B. Winston Jarvis, M.D., New York (Arch. of Ped., Vol. XLVIII, No. 8, August, 1931). Deficiency disease prophylaxis becomes more efficient when vitamin sources are combined in a mixture of such tolerance to the infant's gastro-intestinal tract as to permit its early and continued routine use during the very early months of life, during which time hesitancy is usually encountered in undertaking such a procedure with the more common diversified sources of such administration.

An emulsion of cod liver oil in a concentrated extract of the germinating grains of wheat, oats and malted barley is a mixture exceptionally tolerant to the infant's gastro-intestinal tract.

This emulsion contains Vitamins A, B and D; and lacks C, which should be included by adequate dosages of orange or tomato juice.

Although containing 30 per cent by volume of cod liver oil, this mixture yields a Vitamin D potency equal to that of pure cod liver oil. This is probably due to the greater availability in assimilation due to the complete emulsion by the gastro-intestinal tract and also possibly due to a coördinating activity of the A and B factors.

Within the limits of this investigation, this emulsion supplemented by orange or tomato juice apparently obviates the incidence of clinical deficiency diseases when administered routinely and continuously from six to eight weeks of life.

The author urges the greater interest of the physician in a routine use of cod liver oil emulsified in an extract of germinating grains in infancy and childhood for Vitamins A, B and D prophylaxis.

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

What the Public Should Know About Childbirth. Walker Bourne Gossett, M.D. 290 pages. Cloth. Price, $2.00. Minneapolis: The Midwest Company.

Tables of Food Values. Alice V. Bradley, B.S., Supervisor and Instructor of Nutrition and Health Education, State Teachers College, Santa Barbara, California. 128 pages. Price, $2.00. Peoria, Illinois: Manual Arts Press.

Surgical Pathology of the Genito-Urinary Organs. Arthur E. Hertzler, M.D., Surgeon to the Agnes Hertzler Memorial Hospital, Halstead, Kansas, Professor of Surgery, University of Kansas. 286 pages. Illus. Price, cloth, $5.00. Philadelphia: J. B. Lippincott Company.

TREATMENT OF INJURY BY THE GENERAL PRACTITIONER. Clay Ray Murray, M.D., F.A.C.S., Assistant Professor of Surgery, College of Physicians and Surgeons, Columbia University; Associate Visiting Surgeon, Presbyterian Hospital in the City of New York. 2 Vols., 412 pages of text and 196 drawings by the author. Price, $5.00. Harper and Brothers, Publishers.

This is a monograph in two volumes of convenient size, designed to help the general practitioner in meeting the commoner problems of traumatic surgery. One-fourth of the work is devoted to the treatment of injuries of the soft parts, while the balance deals with fractures and dislocations.

It is a useful guide along these lines, containing much practical advice, tersely told and free from ambiguity. Especially valuable are the sections dealing with the psychology of the patient, the indications for operative interference in bone injuries and the author's own illustrative diagrams.

A few minor changes might be made in later editions. The word "débridement," which really means "unbridling one's horse," should be dropped, and the substitute "épluchage" recommended by Blake is equally misleading, even if literally correct. Why not say "excision"? That is precisely what this author takes pains to describe in detail as the proper mode of cleansing a ragged wound and it is correct and descriptive.

Then the advice to use "the pulmotor or similar mechanical appliance" for artificial respiration is in serious question until we know definitely whether or not these devices cause the air vesicle injury attributed to them by some observers.

But these are remediable matters and do not detract from the general usefulness of the work, which, above all, is to be commended for its evident freedom from cut-and-dried advice and padding of any sort.

Gilbert Cottam, M.D.

AMERICAN PHYSICIANS AND SURGEONS. A Biographical Directory of Practicing Members of the Medical Profession in the United States and Canada. Prepared by James Clark Fifield. Price, $30.00. Minneapolis. The Midwest Company, 1931.

This large volume has been prepared for the use of physicians, hospitals and libraries to supply detailed biographical information regarding reliable and efficient members of the profession. Age, medical education, specialty, articles published, society membership, hospital affiliation are included in the information given.

In the "Foreword" of the volume the editor explains that some doctors are better than others and some are tainted with commercialism. Only those individuals are mentioned who "by reason of their high attainments, skill and reliability are especially entitled to inclusion in such a book." No claim is made that all such are included.

It is explained that final decisions as to inclusion of a name were based on the opinions of the doctors themselves. No doctor can buy his way into the directory.

The editor undertook an enormous task and how well he has accomplished it a reviewer must judge from a perusal of the data about which he is posted. It is probably true, as stated in the foreword, that more errors of omission than commission have been made. A number of names have been omitted which might well have been included. A few errors which need not have occurred were detected: An aurist classified as a general practitioner and two internists listed as graduates of Toronto instead of McGill.

How much of a demand there will be for such a directory at the price is uncertain. We venture the opinion that there will be little demand on the part of laymen in general and few physicians will have enough use for such a volume to warrant the investment.

The thought occurs that it would be well for the A.M.A. Directory to include more information in its volume and thus increase its value.

C. B. Drake, M.D.

MODERN PROCTOLOGY. Marion C. Pruitt, M.D., F.R.C.S. (Ed.), F.A.C.S., Associate in Surgery, Emory University School of Medicine. Cloth. Price $8. Pp. 400, with 233 illustrations. St. Louis: The C. V. Mosby Company, 1931.

This volume rescues Proctology from the esoterica of medicine; it even explains how the specialty got there (see section on hemorrhoids.) One is astonished to learn that the injection treatment of hemorrhoids was practised as early as 1871, by "a man named Mitchell." This obscure and secretive pioneer sold his method to doctors and laymen who went about curing piles, and so were known as "pile curers." Even yet, one may sense the pious fury with which such tactics were met by the profession of that day. By 1914, however, the method was being defended by Sir James Goodheart, consulting physician to Guy's Hospital. Today the method is being taught in the medical schools.

Such conditions as fistula, hemorrhoids, stricture, tumors, prolapse, abscess, et cetera, are taken up in detail; others, such as the diseases of the colon, are less inclusive. Chapters on anatomy, examinations, and anesthesia contain a clear and adequate exposition of the subjects.

E. C. Hartley, M.D.

AN INTRODUCTION TO GYNECOLOGY. C. Jeff Miller. 327 pages. $5.00. St. Louis: C. V. Mosby Co., 1931.

In this work the author discusses etiology, classification, diagnosis, prognosis, general considerations, and clinical considerations of all gynecological conditions. He devotes no time to any form of treatment. The reasons he does so is set forth in his own words in the preface of his work. This work is based on twenty-five years of teaching experience, and it is his object to present something to the student and the beginner which his quarter of a century of teaching has convinced him that they need. The larger works on this subject hardly fit the need of the student, and he feels that the treatment of patients is not the business of the junior student. This is an excellent work for the beginner, and others as well.

A. G. Schulze, M.D.

BEDSIDE INTERPRETATION OF LABORATORY FINDINGS. Michael G. Wohl, M.D., Associate Professor of Experimental Medicine, Temple University Medical School, with an Introduction by Joseph McFarland, M.D., Sc.D., Professor of Pathology, University of Pennsylvania. Cloth. Pp. 320. Illustrated. St. Louis: The C. V. Mosby Company, 1931.

The author says, ". . . this book aims to correlate the laboratory and the clinic. It aims to place a proper evalution upon laboratory reports as applied at the bedside. It aims to omit such tests as are excessively complicated or whose merits are still to be proved, and to emphasize the simpler useful ones that can be performed in his own office by an intelligent practitioner. . . . It aims to emphasize the fact that a laboratory report is only an adjunct to diagnosis, and not the diagnosis itself."

The consistent application of these aims to the twenty-three chapters of the book makes the volume unusually clear and instructive. The chapters deal with the usual subjects of gastric contents, sputum, blood, urine, and so forth, and also with functional tests, acidosis and alkalosis, skin reactions, and pregnancy tests.

E. C. Hartley, M.D.

WANTED—Salaried appointments for Class A Physicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nation-wide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan Ave., Chicago. Established 1896. Member The Chicago Association of Commerce.

REGISTERED NURSE and LABORATORY TECHNICIAN desires position in doctor's office, clinic or hospital. References furnished. Write S. Nilson, 4207 Fremont N., Minneapolis, or call Cherry 6977.

CAPABLE X-RAY, LABORATORY, AND PHYSIOTHERAPY TECHNICIAN desires position. Four years of good experience with hospital and clinic. Can also give ether anesthetics. Can furnish A-1 references. Address D-147, care Minnesota Medicine.

LOCATION: Unopposed practice, town of 750. Will lease with idea of selling out if you like the place. No real estate. German mixed farming community. Very large territory. County seat. Write L. J. Alger, M.D., McClusky, N. D.

WANTED—Position as hospital laboratory technician or physician's office assistant. Experience, and good references. Ruth Swanson, Lindstrom, Minnesota, Box 8.

SCANDINAVIAN PHYSICIAN, recent graduate, licensed in Minnesota, desires location for general practice, or assistantship. Available at once. Address D-148, care Minnesota Medicine.

FOR RENT—Doctor's office, formerly occupied for 25 years by physician. Excellent location. Address C. Stevenson, 2500 Riverside Avenue, Minneapolis.

WANTED—Young German Catholic physician as assistant in country practice in Minnesota. Partnership later if agreeable. State qualifications and salary expected. Address D-149, care Minnesota Medicine.

VOL. XIV NOVEMBER, 1931 No. 11

THE PRESENT STATUS OF THE TREATMENT OF CARCINOMA OF THE UTERUS*

GEORGE GRAY WARD, M.D., F.A.C.S.
Chief Surgeon, Woman's Hospital, New York; Professor of Obstetrics and Gynecology, Cornell University Medical College, New York City
New York City

IN ACCEPTING the invitation to give the "Citizen's Aid Society Memorial Cancer Lecture" before the Minnesota State Medical Association, I am deeply sensible of the honor conferred upon me, and while appreciating greatly the implied recognition of my fitness to speak authoritatively on the subject of cancer, nevertheless I have had much hesitancy in doing so in view of the comparative small field of opportunity we have at the Woman's Hospital as compared to the great radiological centers in Stockholm, Paris, Münich and New York.

These and the other large centers, with their extensive equipment and full time staffs of scientists trained in physical and clinical research, should be the source from which will emanate the knowledge and extended experience which will ultimately enable us to conquer this most dreadful scourge which is an ever increasing menace to the civilized world. Nevertheless, I do not believe that the establishment of numbers of such centers, geographically distributed as has been advocated, will suffice for treating all cancer patients.

These centers will naturally draw to them a large number afflicted with cancer, but even when such special cancer clinics are greatly multiplied, it will never be possible for them to treat the vast number of sufferers who are to be found in every community throughout the land. It is obvious then that for the many patients who cannot be cared for by these centers we must provide proper adequate treatment in our general hospitals throughout the country, and therefore cancer clinics with the necessary facilities and equipment must be established in these hospitals, and members of the staff must be educated to a proper appreciation of the complexities of this disease and trained in the most approved technic, if we are to give the cancer sufferer a chance for his life.

The cancer clinic then in a general or special hospital I believe has a distinct field of usefulness to the community and is an absolute necessity. Furthermore, in these smaller clinics the thorough and complete carrying out of a technic, or line of therapy and follow-up, may often be more possible than in the larger centers on account of the feasibility of a more continuous personal contact between the clinician and the patient throughout the long period of observation necessary.

Regaud, in charge of the Paris Clinic, recognizes this inevitable need for the establishing of facilities for radiotherapy in gynecological clinics, but stresses the importance of a close liaison between each of these clinics and one of the great radiotherapeutic institutions of the country, with which viewpoint I heartily agree as I believe it is to their mutual advantage.

In the whole medical world there is no more important subject requiring prompt solution than the control of cancer. It has been estimated that there are 360,000 people suffering from cancer today in the United States, and it now holds the second place in the cause of death. According to Hoffman in forty-nine cities of the United States the average increase in twenty-five years has been about 2.5 per cent in spite of modern methods of treatment. In New York City the deaths from cancer last year were 113.9 per

---

*Citizen's Aid Society Memorial Cancer Lecture. Read before the Minnesota State Medical Association, Minneapolis, May 5, 1931.

100,000, while in your own city of Minneapolis the high rate of 142.6 per 100,000 was reached, and in St. Paul, your neighbor, the rate was 121.5 per 100,000.

While cancer is a disease that attacks all parts of the body, about 25 per cent of cancer deaths in women are due to cancer of the uterus and the average duration of life is about twenty to twenty-four months when not treated. We, as gynecologists, are especially interested in cancer of the uterus and it is therefore upon that phase of the subject that I wish to speak.

As cancer of the uterus is a type of the disease which every general practitioner encounters in his daily work, it is largely to him that we must look for the early recognition of the disease and the education of his patients to the importance of promptly seeking a diagnosis on the appearance of suspicious symptoms, and as a large number of these patients are being improperly treated today, either by surgery or radiotherapy, by men who have not a proper conception of the complexities of the problem, I propose to give a survey of the present status of the treatment as we understand it in the hope that a more lucid appreciation of the difficulties of the treatment will prevail.

We must appreciate that the disease originating in the cervix and that arising in the fundus must be considered separately, as the clinical course and result of treatment are quite different in each.

CANCER OF THE CERVIX

Cancer of the cervix by reason of the anatomical conditions is by far the most dangerous form and the most difficult to cure, and is also the most frequent. At the outset we must admit that the results of treatment of cancer of the cervix are far from satisfactory, but at the same time we must appreciate that there has been a considerable gain in the percentages of cures and palliations as a result of modern methods. The treatment today resolves itself into a choice of surgery or radiotherapy (either radium or X-ray), and any of these agents may be combined.

Treatment by Surgery.—The early efforts to eradicate the disease was by removal of the cervix, either by cautery, knife or caustic; then followed removal of the entire uterus, as abdominal surgery developed, with nearly 100 per cent of fatal recurrences. It was not until 1898 when Wertheim introduced his extensive radical removal of the uterus, adnexæ, broad ligaments and upper third of the vagina with enucleation of all pelvic glands that any definite improvement in results was obtained, but at a high cost of primary mortality and morbidity.

The difference between the ordinary panhysterectomy and the Wertheim operation may be best appreciated when likened to a simple mastectomy as compared to the modern radical removal of the breast with the pectoralis muscles, and the thorough cleaning out of the axilla of the lymphatic glands. A simple mastectomy for cancer of the breast would not be considered justifiable surgery today, yet I know that scores of women with cancer of the cervix are being subjected to an ordinary hysterectomy instead of the radical operation, due to the fact that the average general surgeon is not competent, owing to lack of experience and failure, to develop the necessary skill, or he fails to appreciate what the technic of the radical operation should be. I have seen Wertheim and many of the foremost exponents of his technic do the operation, and I have done many myself, and I speak knowingly when I state that I have seen operations that were called Wertheim's that in no way fulfilled the requirements of that technic.

One of the outstanding surgeons in this particular field today is Victor Bonney of London, and I would commend his recent Hunterian Lecture on the "Surgical Treatment of Carcinoma of the Cervix" to those who wish to obtain a proper appreciation of the technic and the difficulties of this formidable operation. The vaginal route was also popularized by Schauta for the wide removal of the uterus and attachments, made possible by the use of the extensive Schuchardt incision. In the first place we must appreciate that the Wertheim operation or the Schauta operation can only be employed in less than half of those applying for treatment, as it must necessarily be limited to the operable class, variable as this class may be in different hands. For the other half surgery offers nothing.

There is no difference of opinion as to what is the best treatment at our disposal for the inoperable class. Radiotherapy is admittedly our most valuable palliative measure, definitely prolonging life and in a small percentage of cases, approximately 12 per cent, accomplishing a cure.

Results with Surgery.—What can we hope to accomplish with the Wertheim operation in the most skilled and experienced hands in this less than 50 per cent of patients with cancer of the cervix that come to us?

Lane-Claypon's exhaustive study, published in 1927, of 80,000 cases in the literature, shows that about 37.6 per cent of five-year cures have been salvaged, but if all the patients applying for treatment are considered, the percentage is 18.3 per cent with a primary mortality of 17.3 per cent.

In the same year Heyman of Stockholm published a masterly study of the operative and radiologic statistics of the leading clinics of Europe and this country. He reduced the figures to a uniform standard. The operative results in twenty clinics showed a total cure rate of 18 per cent and an operable cure rate of 35.6 per cent, but with a primary mortality from the operation of 17.2 per cent.

Weibel in 1928 reports on 1,500 cases operated in Wertheim's Clinic out of 3,165 seen (47 per cent) with a five-year cure rate of 38.4 per cent on those operated, an absolute cure rate of 19.2 per cent on all cases seen, and an average primary mortality of 13.8 per cent.

Victor Bonney's recent report of his results shows that he had seen 450 cases and operated on 284 with a primary mortality of 16.5 per cent, a relative five-year cure rate of 37.8 per cent and an absolute cure rate of 24.4 per cent. His primary mortality in his last ninety-eight cases was 8.1 per cent.

Lane-Claypon states that the extended abdominal operation and radiation are the only methods in serious competition at present. Recently, however, Stoeckel, Adler, and others have been employing the Schauta vaginal hysterectomy combined with radiation, but up to the present the time is too short for any comparative evaluation.

Treatment by Radiotherapy.—In 1929 was published the report of the Radiological Sub-Commission of the Cancer Commission of the League of Nations which gives the guiding principles, technic and results of radiotherapy in carcinoma of the uterus at the three great radiological clinics of Stockholm, Paris and Münich. Every surgeon who contemplates employing radiotherapy in the treatment of carcinoma of the uterus should be thoroughly familiar with the contents of this publication of the League of Nations. It can be readily obtained, published in English, and while the technic employed in these clinics shows considerable variation, the principles of the physical and biological factors involved are in accord, and the results obtained are nearly the same. A perusal will quickly show the novice in radiotherapy that it is no simple matter to employ this two edged weapon efficiently and at the same time safely in the treatment of carcinoma of the uterus.

The technic of the application of the radium in these cases seems so simple that it is difficult to impress upon the casual observer that success and safety depends on the careful study of the location and extent of the disease, of the type of cell and the degree of its maturity, of the general physical state of the patient as to age, blood condition and toxemia, of the careful preoperative preparation of the patient, of the amount of radium used and its distribution in appropriate containers, on the proper employment of screening to cut out the burning rays, on the placing and maintaining of the radium *in situ* where it will destroy the cancer and yet not damage adjacent viscera, on the duration of the application, and the time and dosage of reradiations and deep X-ray therapy, and finally on a careful frequent follow-up. A personal experience in studying the action of radium on this disease over considerable periods of time is essential before one can become competent to properly treat cancer of the uterus with radiotherapy. I say this in spite of the assurances given the practitioner in the alluring advertisements in the medical press, that it is so simple that all he has to do is to send a description of the case and they will send the radium with full directions. Correspondence Courses in radiotherapy are dangerous and we wish to sound a warning as to the serious harm that may result from the indiscriminate application of radium by the inexperienced. I have seen a number of instances of grave permanent damage being done through the careless and ignorant use of radium by those not qualified. The renting of radium from commercial agencies is of course perfectly justifiable, but the knowledge and judgment as to how and when to use it can only be bought by careful study and personal experience and observation in radiological clinics. I cannot do better than quote Regaud's recent warning, "It is necessary to have much experience to obtain from this method of treatment all the good that it may give without the evil that it may do."

The Action of Radium.—The effect produced by the action of radium upon malignant or normal cells should be familiar to all who use this element. Radium does not remove a cancerous growth by destruction of the entire part affected as is accomplished by surgery or cautery, but the gamma rays have a direct selective action on the cancer cells destroying them without injuring the normal cells at the site of the neoplasm. This is often demonstrated in healed cases of carcinoma of the cervix, where the normal shape of that organ may be restored with no trace of the site of the growth. Another action of radium is to cause the proliferation of connective tissue. The connective tissue, contracts with the resulting obliteration in great degree of the blood and lymph supply, producing the contracted, pale looking cervix and funnel shaped vaginal vault, that we see in the ideally healed cases.

Thus we must appreciate that if the dosage suitable for a certain case is used, we will destroy the cancer cells but *not* the normal tissues, owing to the selective action of the gamma rays on the carcinoma, and the greater resistance or toleration of the normal tissues. However, it must be born in mind that if we give much larger doses of radium than is required to destroy the cancer cells, we will also destroy the normal structures and produce extensive necrosis with its resulting septic absorption, hemorrhages, and injury of adjacent viscera with perhaps the formation of fistulæ. Remember also that these unfortunate results of over-radiation with this powerful element are commonly attributed to the extension of the carcinoma, or frequently the action of the radium is blamed and consequently condemned as of no value.

We must see also that if too small an amount of radium is used, or for too short a time, that we may fail to destroy all the cancerous tissue.

Upon the proper screening of the radium depends the elimination of the Beta, or burning rays, which cause extensive destruction of the normal tissue. Various metal containers of different thickness are used such as platinum, gold, silver, or brass for this purpose, and the integrity of the bladder and rectum is accomplished by "distance screening," that is pushing them out of reach of the rays by over distending the vagina with gauze. If inadequate screening has been used, unnecessary necrosis will result.

Too frequently repeated radiations, especially if a heavy dosage for prolonged periods are employed, will result in the so called "late reaction" of radium. Six months, or a year or more, following the initial treatment dense infiltration, pelvic pain, ulceration and discharge may develop which is apt to be attributed to a *recurrence* of the disease, when actually it is the result of an over-irradiation of the tissues with resulting excess of connective tissue formation. This produces a slowly developing obliterating arteritis, and the devitalized structures ulcerate and become a ready prey to infection.

Considerable work has been done in this country in studying the type of cancer cell and the effect of the radium on the several varieties in the hope that a guide to the prognosis might be found. Broders, Martzloff, Greenough, Schmitz and others have made valuable contributions to this subject.

Two main histological types of cervical carcinoma are recognized, the epidermoid carcinoma and the adeno-carcinoma. The epidermoid carcinoma, which is much the most frequent, is divided into three classes according to the differentiation of the type of cell. The epidermoid group is the most common form, and the cell types are designated as the squamous or spindle cell, which is the most mature or "ripe" cell, the transitional or plexiform "midripe" cell, and the anaplastic spindle, "unripe" cell.

The adeno-carcinoma is chiefly recognized by its glandular form of growth.

The importance of recognizing these various types of cancer cell will be appreciated when we understand that they respond differently to irradiation. The "Law of Bergonie and Tribondeau" states that "Immature cells and cells in an active state of division are more sensitive to irradiation than are cells which have acquired their fixed adult morphologic and physiologic characters." The squamous spinal, or mature cell is much the more radio-resistant and at the same time is more slowly growing and the least malignant type, while the embryonic anaplastic "unripe" spindle cell is the least radio-resistant but the most rapidly growing and most malignant type. The transitional or "midripe" cell is midway between these two extremes in responding to irradiation. The adeno-carcinoma of the cervix is fortunately much less frequent (our ratio is about 13 to 1), as it is very radio-resistant and more difficult to cure.

The ability to make a prognosis as to the probability of obtaining a cure by studying the type of cell is open to debate and is not uniformly accepted, as it is evident that many other factors must be taken into account, notably the extent of the disease and the physical resistance of the patient, and also that the ordinary biopsy does not allow of a study of the complete specimen which may show considerable variation in the type of cell differentiation in various regions.

From what has been said it must be evident that the ideal irradiation should be a dosage adjusted to the type of cell we are dealing with and to the extent of the disease, which, while sufficient to destroy all the carcinoma cells, yet should not damage the normal tissues beyond repair. Schmitz has attempted to standardize the dosage according to the cell type, giving a 100 per cent erythema skin dose with combined radium and X-ray for the embryonic unripe cell, and 150 to 175 per cent for the squamous adult cell. He states that the normal tissues will bear without permanent injury an erythema skin dose of 150-175 per cent. The 100 per cent dose may be represented by 3200 milligram hours of radium, 150 per cent by 4800 milligram hours, and 175 per cent by 5600 milligram hours, the latter being the utmost limit for normal tissues.

Large quantities of radium then are not of advantage for internal application. The curative penetration of the gamma rays is limited to about 3.5 centimeters in the amounts that we may safely use. Necrosis of tissue may be caused at the site of application by the gamma rays breaking up into secondary rays from the metallic screens and their action on striking the tissues. We attempt to limit the action of these secondary rays by aluminum or pure rubber protection. It does not avail us to attempt to secure a deeper penetration in an effort to reach the parametrium by greatly increasing the amount of radium in the container, because the intensity of radiation is decreased inversely in proportion to the square of the distance, and the result we would obtain would be a marked and unnecessary increase of the local damage without appreciable gain in penetration.

Toxemia.—The physical condition of the patient may have an important bearing on the reaction produced by the radiotherapy. Many of these patients are anemic and cachectic, and suffering from toxemia as a result of the absorption of necrotic carcinomatous tissue. Frequently they are septic due to a local infection of the ulcerated areas. The immediate result of the radiotherapy in such cases is to produce a severe reaction on account of the absorption of the autolytic and toxic protein substances which have been liberated by the destruction of the cancer cells.

This "radiation sickness" is naturally more severe in those cases that are already toxic and anemic, and this systemic condition prevents the defense mechanism from promoting the prompt healing of tissues. The effect of the radium is to produce a leukopenia and the patient's resistance needs to be fortified to combat this condition. Hence the value of blood transfusions to enable the patient to weather the storm and make a smoother recovery.

External Radiation.—As the beneficial action of the gamma rays of radium is limited to a range of 3 to 4 cm., it is apparent that if the cancer has spread beyond this distance, that the local radium application will not be sufficient to eliminate the disease. Bonney found 43 per cent of gland involvement in his operative cases, and it is to this that he attributes the superiority of surgery.

External radiotherapy by means of the high voltage deep X-ray or by using a radium pack, or "bomb" at a distance, is necessary to attack the disease when beyond the reach of the internal radiation. The use of radium at a distance requires a large amount of radium, 2 to 4 grams, so that the method is not available except in a few radiological institutions.

According to Regaud the use of radium at a distance for external radiotherapy is more desirable than the deep roentgen rays as the short gamma rays of radium are undoubtedly more selective in their action than X-rays. He states that if normal tissue and cancer tissue are exposed equally to radium and the X-rays, it will be seen that while there is an equal destruction of the cancer cells, there is less change observable in the normal connective tissues with radium than the X-ray.

Nearly all radiologists are agreed that the combined treatment is necessary to obtain the greatest benefit, although the results secured in the Stockholm Clinic and our own clinic have been accomplished largely without the X-ray, until recently. Heyman has just published a report of the Stockholm results with the combined treatment which shows a definite improvement over their previous experience, and he states that this technic now will be their routine method. At the Woman's Hospital, we did not have the high voltage apparatus until the past two years, and we are at present using the combined method in the advanced cases.

The Limitations of Radiotherapy.—To find the balance between the dosage necessary to completely destroy the neoplastic cells, and at the same time keep within the minimum dosage which will destroy normal tissues, is the problem that the radiologist must meet. It is obvious that the conditions in each case may vary greatly. The type of cell, the physical characteristics of the growth, the size and condition of the organs affected and the constitutional state of the patient are all factors which must be carefully weighed in planning the dosage and technic best suited for the case under consideration.

Regaud has pointed out that radium is not a cure for every case of cancer. It is with the epidermoid type that the best results have been obtained. The adeno-carcinoma group are more difficult to cure. In the cases where the parametria are involved, the proportion of five-year cures is small, although the palliative results, even in many advanced cases, are of great value in prolonging life and reducing suffering.

Healy states that they have found that 80 to 85 per cent of all their carcinoma of the cervix cases were in the advanced stage.

Results with Radiotherapy.—What can we hope to accomplish in treating carcinoma of the cervix with radiotherapy?

When we speak of a "cure" we must understand we mean that the patient is clinically free of cancer not less than five years after commencing the treatment. In the report of the Sub-Commission of the League of Nations in 1929, Heyman shows that at the Radium-Hemmet, Stockholm, they had treated 737 cases of carcinoma of the cervix with an absolute cure rate of 20.6 per cent and a primary mortality of 2.1 per cent, and a relative cure rate of 23.1 per cent. Twenty-five and one-half per cent of these cases were classed as operable with a cure rate of 40.4 per cent, and 66.7 per cent were inoperable with a cure rate of 13 per cent.

Lacassagne reports for the Radium Institute of Paris on 350 patients treated by radiotherapy alone with an average cure rate of 20 per cent. Forty-two per cent were cured where the disease was limited to the cervix, and 10 per cent in the advanced cases. Regaud in an address given in November, 1929, shows that while their average cure rate for their total cases was 20 per cent, that there has been a steady improvement in their salvage each year from 10 per cent in the 1919 series to 30 per cent in the 1923 series, and the indications as shown by their provisional results point to a still higher percentage of cures in subsequent series.

Voltz reports for the Münich Clinic that 1319 patients were treated from 1913 to 1923 inclusive, with an operability rate of 17.2 per cent. The absolute cure rate for these cases was 15.4 per cent. For the cases with the disease limited to the cervix the cure rate was 40.5 per cent, while for the inoperable group the salvage was 10.7 per cent. Voltz shows that since 1920, when the combined internal and external radiation has been in use, that there was a definite improvement in results by combining radium with X-rays, and in their fully treated cases their absolute cure rate by their recent technic is 21.4 per cent.

The Memorial Hospital in New York results as reported by Healy in 1928 shows 50 per cent five-year cures in the early cases and a 25 per cent relative cure rate. Bowing and Fricke in a recent report from the Mayo Clinic show that of 626 cases treated by radiotherapy only, they had an absolute cure rate of 21.08 per cent, and a relative rate of 23.15 per cent, while with the operable group the absolute rate was 60.86 per cent.

It is also interesting to note that Wintz has reported 17.1 per cent five-year cures by deep X-ray alone in 415 cases, and Adler states by the combined vaginal operation with radium and X-ray that he has a cure rate of 32 per cent in 256 cases with a primary mortality of 3.6 per cent.

At the Woman's Hospital, New York, we have been treating carcinoma of the cervix with radium since February, 1919. In October, 1930, we presented our results for the period from 1919 to 1924 inclusive at the meeting of the

American College of Surgeons. During this period we have seen 259 cases; eight of these were refused radium treatment because of a hopeless condition, and 251 patients were treated with radium. Of these 251 cases the disease was limited to the cervix in 65 (Class I and II, Schmitz), an operability rate of 25.9 per cent. In 186, the disease had extended beyond the cervix (Class III and IV, Schmitz), an inoperability rate of 74.1 per cent.

The ages of the patients ranged from twenty-four to seventy-six years. There were 15 patients under thirty years of age.

Our primary mortality in 361 radium applications was four deaths or 1.1 per 100 applications. There were no deaths in the Class I and II cases.

The five-year end-results of these cases were sixty-four living patients, giving an absolute cure rate of 24.7 per cent and a relative cure rate of 25.5 per cent.

Of the 251 cases, 170 were treated only by the technic we have developed. In this group 79.4 per cent were suffering from an advanced type of the disease (Class III and IV).

Forty-four of these 170 patients of all classes of the disease were living at the end of the five-year period, or 25.9 per cent; of the Class I and II cases (limited to the cervix) of which there were 25, 20 were living or 57.1 per cent; of the 135 Class III and IV cases (advanced beyond the cervix), twenty-four were living, or 17.7 per cent.

In 251 cases treated we were able to trace all but nine, or a completed follow-up of 96.4 per cent. The lost cases were classed as dead of cancer.

ESSENTIALS OF THE WOMAN'S HOSPITAL METHOD

During the first year our technic was not systematized and was therefore variable and was sometimes combined with surgery, but since 1920, we have consistently followed a technic that we have developed. This technic we have previously published in detail, the essential features being: the preliminary building up of the patient's resistance when indicated; an initial test dosage of radium of 2,400 to 4,200 milligram hours is given and we watch the result, subsequent irradiations being dependent on the reaction; a meticulous postradiation care of the patient, with a personal monthly follow-up throughout the entire five-year period, with re-radiations whenever the follow-up examinations disclose evidences of beginning recurrence that are within reach. We have not used the high voltage X-ray therapy as an adjunct until the past two years, so this factor does not enter into the six series reported.

Our experience has led us to believe that improving the patient's resistance before the irradiation in cachectic cases is of distinct advantage in enabling the patient to pass through the period of post-radium reaction safely. Therefore whenever possible every patient with red cells less than 3,500,000 and hemoglobin 50 per cent or below, is given a blood transfusion prior to the application of radium.

We have found that spinal anesthesia, a half dose only being necessary, is more desirable than a general anesthetic in these cachectic cases when inserting the radium. Potassium permanganate douches and an elevated posture are begun at once to favor drainage and separation of any post-radiation slough.

The value of a personal follow-up each month we believe cannot be overestimated. In no other way is it possible to detect early recurrences as manifested by small nodules or erosions long before the patient is aware of any subjective symptoms. Thus we are enabled to give a re-irradiation with tube or needle in time to check the recurrence while in its incipiency.

Re-Irradiations.—The outstanding feature of our method of treatment is this re-irradiation whenever our monthly follow-up inspection reveals evidence of recurrence in the vaginal tract, during the entire period of five-year observation. Nearly 50 per cent of our cases have had repeated irradiations. This is of interest because repeated applications of radium after the initial treatments, are not the usual practice in radium clinics, due to the fear of producing late radium necrosis as a result of the radio resistance of the tissues being increased by over-irradiation. This danger in our belief occurs only if prolonged and repeated applications of a heavy dosage are used. This we try to avoid. Our employment of re-irradiations after the initial treatment is largely for metastatic outbreaks in the vaginal walls or fornices, and consists of a relatively small dosage usually in the form of platinum needles, although should the nature of the recurrence make the use of a contact application more desirable we do not hesitate to use tubes or flat containers. The average dose ranges from 300 to 1,200 milligram hours, depending on the size and location of the metastases. Very few clinics have such a frequent follow-up continued throughout the five years, and it is to this that we attribute our success in saving some cases by discovering recurrences early. We have many instances of successful irradiation of such metastases, occurring two, three, and four years, or longer after the initial treatment, our cure rate for these cases being 26.5 per cent.

We are encouraged to continue this practice in spite of some criticism, as our results seem to justify it, and as several authorities have recently reported the use of this procedure. Heyman in an address before the Royal Society of Medicine in 1929 states that, "We have in recent years in cases of persistent small residua and in the cases of smaller vaginal recurrences made use of intubation of radium needles." The Marie Curie Hospital of London reports that they give repeated irradiations in certain cases with improvement. Taussig in a discussion before the American Gynecological Society last year spoke of the value of re-irradiation, stating that they had caught recurrences in a very early stage and have been able to save and prolong life thereby. In this connection it is interesting to note that in the Münich Clinic the standard treatment is to give a second irradiation eight weeks after the first and if the follow-up shows it necessary a further treatment after an eight weeks interval. Voltz states that no case of theirs survived that did not receive the second treatment two months after the first.

We wish to emphasize the danger of re-irradiating cases with a late radium reaction, under the mistaken impression that there is a recurrence of the carcinoma.

SURGERY VERSUS RADIUM IN CARCINOMA OF THE CERVIX

While exceptional operators like Bonney may attain a slightly higher rate, the highest average figure for the Wertheim Operation in experienced hands is about 20 per cent absolute cure rate. The average absolute cure rate for radiotherapy as reported by the radiological clinics fully equals this. The 50 per cent that apply which cannot be operated upon because of the extent of the disease, have nothing to hope from surgery. From radiotherapy they may look for a 12 per cent cure and definite palliation with prolongation of life in most cases.

Lane-Claypon's study shows that the primary mortality of the radical operation averaged 17.3 per cent for all cases and the more advanced the disease the higher the rate, contrasted with a primary mortality rate of less than 2 per cent for radium, and that on the basis which includes all cases applying for treatment the results obtained with radiotherapy show a somewhat higher proportion of successes than are obtained with surgery.

While the question of radium versus surgery in the operable cases is still debatable, it must be granted that radiotherapy has a strong position in view of the results that have been accomplished by this method. A 57.1 per cent salvage in early cases with no primary mortality, which we have obtained, compares favorably with Bonney's recent report of 38.7 per cent and a primary mortality of 8 to 16.5 per cent with the Wertheim operation, admitting that he operates on many cases where the disease has extended beyond the cervix, and our absolute cure rate of 24.7 per cent is about equal to the 24.4 per cent which he reports.

Regaud in his address given at Liverpool controverts Bonney's claim of the superiority of surgery when it is a question of the invasion of lymph glands, and states that their statistical results justify this claim. By the association of roentgentherapy with the internal use of radium in advanced cases he believes that percentages of lasting cure have been obtained which surgery cannot equal.

Surgery has reached its zenith in the hands of experts after years of experience, and we cannot hope for much further improvement in their results. Radiotherapy on the other hand is as yet in its infancy and we can look forward with confidence to a continued improvement in results as our experience and technic develop.

In summarizing the case of surgery versus radium for carcinoma of the cervix, we may say that while there are differences of opinion as to which method gives the best results in those cases that are in the operable class, there can be no dispute as to the more than 50 per cent of inoperables. For these cases radiotherapy is our most valuable agent today with its undoubted palliative worth and a cure rate of more than 12 per cent. As to what cases are to be classed as "operable" will always be debatable, as the personal equation must enter into the problem. Consequently the comparison of statistical reports from different clinics must be of uncertain value in estimating the results of treatment in this group. Only the final end results of the total cases seen can be accurately appraised.

CANCER OF THE FUNDUS

About 10 per cent of cancer of the uterus originates in the fundus and is usually of the adeno-carcinomatous type of cell. It is more frequuent after the menopause, the mean age incidence being about eight years higher than the cervix cases. It is generally agreed that the ordinary pan-hysterectomy gives such a satisfactory cure rate that it is the method of choice. Lane-Claypon states that the operability is about 80 per cent, and the five-year survival rate is about 60 per cent. However, many of these patients are poor operative risks due to old age, obesity, cardio-vascular disease, deficient renal function, or diabetes. These complications were present in over 50 per cent of our cases.

Radiotherapy must then be relied upon. The Stockholm Clinic report 43.5 per cent cure rate with radium alone in forty-six cases. Healy and Cutler report 58.5 per cent cures in eighty-two cases with radium at the Memorial Hospital, New York. We believe that the ideal method is to combine radium with surgery in these cases wherever possible.

CONCLUSIONS

Progress in the conquest of cancer of the uterus depends not only on advances in technic and therapy, but upon earlier diagnosis. The earlier the case is treated the greater the chance of a cure and with less danger. At present 80 to 85 per cent of patients applying are in the advanced stage. We must look to the general practitioner to make these early diagnoses and to educate his clientele to the importance of promptly seeking advice for suspicious symptoms.

It is just as necessary that men should be properly trained in the treatment of cancer of the uterus by radiotherapy if satifactory results are to be obtained, as that they should be properly trained in surgery.

SUMMARY

1. I believe that the best statistical reports show that radiotherapy is preferable in all classes of carcinoma of the cervix, although I believe that the radical operation will give as good results as radium in the early cases, but at the high cost of primary mortality and morbidity.

2. There is less primary mortality, less morbidity, less loss of time with radiotherapy than with the radical operation for carcinoma of the cervix.

3. The morbidity results of the radical operation should not be forgotten.

4. Radiotherapy in the advanced cases has no rival with a 12 per cent salvage and as a palliative measure.

5. Re-irradiations, when properly employed, are of definite value in curing local metastases throughout the five-year period of observation.

6. A frequent personal follow-up throughout the five-year period is necessary in order to make possible the early discovery of local recurrences, and to permit of prompt re-irradiations.

7. Carcinoma of the fundus is best treated by the combined use of radium and surgery whenever possible.

8. The early treatment of cervical injuries and disease is an important prophylactic measure.

9. The upward trend in the death rate from cancer calls for a compulsory registration of all cases.

10. It is to be deplored that many women with cancer of the cervix are hopelessly doomed, because they are submitted to obviously useless and obsolete surgical procedures, or have been improperly treated with radiotherapy.

11. Finally, I wish to emphasize that if surgery is used for carcinoma of the cervix, only the radical Wertheim operation is justifiable and that this requires experience with a highly specialized technic. If radium is used, experience and a thorough understanding of the action of this powerful agent and a full appreciation of the complexities of its safe and efficient application is essential, otherwise we assume a grave responsibility in not giving these patients a chance for their lives.

RECENT DEVELOPMENTS IN THE TREATMENT OF DUODENAL ULCER*

Donald C. Balfour, M.D.
Rochester, Minnesota

SURGERY occupies an undisputed place in the treatment of chronic duodenal ulcer. Although it is often difficult to determine the best plan of treatment in certain stages of the disease, in many cases the disease has progressed to a stage at which there is no question but that well applied surgery offers more to the patient from every standpoint than does any other method of treatment. Long-continued disability; intractability to treatment; acute, subacute and chronic perforation; obstruction; recurring hemorrhage, and severity of symptoms, are all clear indications for operation. When this is properly carried out, it will, in a high percentage of cases, give complete and permanent control of the disease, its symptoms, and its complications.

The present practice of postponing operation until such conditions as those named have developed is sound in that there can be no doubt as to the wisdom of operation under such circumstances. I believe that further experience will show that surgical measures can be applied in earlier stages of duodenal ulcer, to the benefit of the patient, particularly in relief of symptoms and protection against the complications of the disease. Frequently the disease has been of long duration, and extensive induration and deformity of the duodenum has taken place. Therefore, gastro-enterostomy is most often the operation of choice because its rates of mortality and morbidity are low, and because it can be relied on to give excellent results when employed in such cases.

Gastro-enterostomy, however, even in cases of long standing, is not always the best operation. It is because of the possibility of earlier operation being advantageous, and because of certain other indications for direct procedures for lesions of the duodenum, that I wish to consider the place which these direct procedures hold in the treatment of duodenal ulcer. The term direct procedure is applied to an operation which includes removal of the lesion or lesions in the duodenum and reconstruction of the pyloric outlet.

There are certain inherent advantages in direct operations for duodenal ulcer, which should always be kept in mind. First, when direct operation is done in cases which are carefully selected, it will be associated with a lower mortality rate than that of any other operation for duodenal ulcer. This statement, although true, is misleading, since gastro-enterostomy is chosen in those cases in which operation is of increased risk, because of the poor condition of the patient, marked obstruction, the presence of extensive inflammatory products, and so forth. Gastro-enterostomy is then a safer procedure than any method of excision and pyloric reconstruction. It would, therefore, be more accurate to say that direct operations are of least risk when they are used in cases in which they can be done safely. Second, the possible advantages of removal of the lesion or lesions must be considered. Theoretically, these are advantages, but in actual fact they cannot be very definite except in those cases in which the ulcer has been associated with bleeding. I am aware of the theory propounded by exponents of partial gastrectomy that an unremoved duodenal ulcer may act as a focus and be responsible for formation of a new ulcer. This possibility must be slight since the most certain result of well performed gastro-enterostomy for chronic duodenal ulcer is permanent healing of the ulcer. Any real value in removal of whatever lesions are present in the duodenum is chiefly confined to the hemorrhagic type of ulcer. Third, direct operation for duodenal ulcer usually permits inspection of the posterior wall, and the information thus acquired as to the extent of the disease is of unquestioned value in the intelligent management of the case. Fourth, in the event of recurrence of ulceration after direct operation with reconstruction of the pyloric outlet, further surgical treatment is not difficult.

The first indication for direct operation for duodenal ulcer, then, is that it can be safely and satisfactorily done. Decision as to the advisability of attempting excision of the lesion varies with the experience of the surgeon; the greater his experience, the larger the number of lesions he will find removable. Primarily, a satisfactory direct operation depends on the situation, size and number of the lesions, the type of perforation, the accessibility of the duodenum, and the amount of scarring which has taken place in the walls of the duodenum. Direct operation, therefore, is usually contraindicated in those cases in which multiple lesions are so situated that they can be removed only with great technical difficulty and consequently increased risk. When a lesion of the posterior wall is large and has perforated deeply into the head of the pancreas, when great deformity of the duodenum exists, when diffuse scarring has narrowed and shortened the first part of the duodenum, when extensive involvement of periduodenal tissues, or gallbladder, or liver, has occurred, or when marked obstruction is present, any attempt at direct operation is usually contraindicated.

---

*Read before the Minnesota State Medical Association, Minneapolis, May 5, 1931.

The type of case in which the direct operation is most commonly employed is in the young patient with a nonobstructing ulcer or inflammatory process of the anterior wall, with marked hyperacidity, and a small, high-lying, hypertonic stomach. In such cases, although gastro-enterostomy will usually give a good result, the danger of recurrence of a lesion in or near the stoma is unquestionably greater in other types of cases. On this score, excision of the lesion and reconstruction of the pyloric outlet have obvious advantages, and they should be done when any operation appears indicated in such cases, even though technically they are difficult. A most important feature of these early cases is that the only visible evidence of pathologic change in the duodenum is an inflammatory process of varying extent, without any true ulceration of the mucosa. Judd has emphasized this condition of duodenitis and the value of wide removal of the inflammatory portion. It is also common to find after removal of these nonulcerating lesions of the anterior wall other lesions, or a lesion in one stage or another, on the posterior wall. This multiplicity of lesions presents a problem which I shall consider later.

Direct operation must always be considered in those cases in which hemorrhage has been an associated symptom. There is no doubt that greater protection against subsequent hemorrhage is afforded the patient if lesions are removed than if they are not removed. This fact often gives rise to an interesting surgical problem, when, because of multiplicity of lesions, or the situation or extent of a lesion, removal becomes an operation of obviously increased risk. I am convinced that when such added risk is real, it is better to perform gastro-enterostomy, with a risk of less than 1 per cent, and with good prospects of satisfactory healing of the ulcer, than to attempt excision. In those cases of hemorrhagic ulcer in which direct operation can be carried out without prohibitive risk, the advantages of visualization of the posterior wall are very important, since it is usually a lesion of the posterior wall which is responsible for serious or fatal hemorrhages. I shall refer to the treatment of such lesions later.

Acutely perforated duodenal ulcers are occasionally best dealt with by direct operation. Simple closure of a perforation, done within the first six hours after the perforation has occurred, practically always saves the life of the patient, but many of these patients will have recurrence of symptoms sufficiently severe to demand subsequent operation. Gastro-enterostomy at the time of the closure often adds unnecessary risk to the operation. Excision of the perforated ulcer with the surrounding inflammatory duodenal wall, and reconstruction of the pyloric outlet can be done, I am convinced, in many cases, without increased risk and with excellent prospects of permanent protection against recurrence. I recently operated on a patient twelve hours after perforation of a duodenal ulcer which had produced almost complete obstruction. The entire inflammatory region could be readily excised, and the pyloric outlet reconstructed so as to provide a large lumen, with complete relief of the obstruction.

The direct operation for duodenal ulcer is particularly well applied in the treatment of gastrojejunal ulceration. The primary requisite in operation for gastrojejunal ulceration is removal of the lesion and disconnection of the gastro-enteric stoma. It is also necessary, however, to consider what is best to control the activities of the duodenal ulcer for which the gastro-enterostomy was done. Usually the primary lesion has completely healed, and it is occasionally advisable to do nothing for it, but a regimen for the patient to live by should be established and, should reactivation of the primary lesion take place, some surgical procedure should be carried out later. In many cases it is possible to prevent reactivation of the disease by a reasonable regimen. It is usually preferable, however, at the time the gastrojejunal ulceration is dealt with, to carry out some procedure for the primary duodenal ulcer, particularly if it is of the contracting type. Excision of the ulcer, with reconstruction of the outlet, possesses great advantage under such circumstances. First, the operation adds little to the risk, and, second, it avoids the serious problem of recurrent ulceration following partial gastrectomy. In the few cases in which gastrojejunal ulceration develops following well indicated and well performed gastro-enterostomy, the patients demonstrate unusual liability to the development of ulcer; this fact should be constantly kept in mind in selecting the type of operation for the duodenal ulcer. It is for this reason, also, that excision and reconstruction of the pyloric outlet has such signal advantage, for should recurrence of ulcer follow, great flexibility in surgical treatment is possible; this is in contrast to the difficulties and restrictions of treatment of the recurrent ulcer in the resected stomach.

The methods of accomplishing direct operations for duodenal ulcer are numerous. Finney gave great impetus to such operations with his pyloroplasty. Many modifications of this have been made with the purpose of meeting the various conditions found. In principle these procedures are the same, and they provide for removal of the lesion, ablation of the pyloric outlet, and reconstruction of the outlet so that an adequate lumen will be permanently established. Wide removal of the anterior portion of the pyloric muscle and the cap of the duodenum, as emphasized by Judd, adds definitely to the prospect of building up a satisfactory outlet. The preliminary steps in the operation are most important, since satisfactory mobilization of duodenum and pylorus has much to do with completing the operation safely. Sutures placed through the pyloric muscle, at the lesser and greater curvatures, serve as excellent tractors and as means of controlling bleeding when the muscle is severed. A very useful procedure is first to open the stomach midway between the curvatures, and about 2.5 cm. above the pylorus, introduce the finger, and examine the posterior wall of the duodenum. Occasionally a lesion of the posterior wall may be found to be so situated, and of such a size, that excision seems unwarranted; gastro-enterostomy thereby becomes the operation of choice. The opening in the stomach can then be closed, and the gastro-enterostomy performed. If it is advisable to proceed with local excision, the finger may be used as a guide, and the pyloric muscle divided just to the inner side of the stay sutures; then the anterior wall is inspected and if a lesion is found, as is common, it is excised with the cautery and the defect closed with two rows of continuous chromic catgut, the suture beginning and ending in the stump of the pyloric muscle. Interrupted sutures of chromic gut reinforce the suture line. The pyloric end of the stomach is then sutured to the round ligament of the liver, as recommended by W. J. Mayo. The risk of this procedure is less than 1 per cent and the results in relieving the patient of symptoms, protection against recurrence of ulceration, and its complications, give it a fixed place in the surgical treatment of chronic duodenal ulcer.

PHLEGMONOUS ENTERITIS

E. Mendelssohn Jones, M.D., F.A.C.S.
Saint Paul

A PHLEGMONOUS affection of the gastro-intestinal tract carries a very high mortality and fortunately is not commonly encountered. In 1906, MacCallum found that only seven cases had been described. Five of these involved the upper part of the small intestine, one the colon and another the whole digestive tract. Since this report the majority of the other recorded cases substantiate the fact that the lesion is most common in the small intestine and particularly the duodenum and upper jejunum.

Phlegmonous enteritis is similar pathologically to phlegmonous gastritis and phlegmonous colitis. It may occur as a secondary manifestation in connection with such conditions as a strangulated hernia or intussusception where mechanical interference with the bowel or its circulation has taken place. All of the cases cited by MacCallum ended fatally. Hughes and Zoepffel each report one case of phlegmonous enteritis with recovery after resection. In phlegmonous inflammation of the large intestine Dowd has a recovery after resection of the diseased bowel. Wilson reports a case of phlegmon of the jejunum with recovery following a lateral anastomosis between the jejunum above and below the lesion.

Primary phlegmonous enteritis is exceedingly rare but the secondary type is more common. It occurs more frequently in the male sex and has been observed between the ages of six and seventy-five. In all cases the existing cause is a pyogenic organism and usually of the streptococcic type.

In discussing phlegmonous duodenitis Black points out that individuals suffering from severe burns and septicemias do, in rare cases, develop ulceration of the duodenum. After artificial production of septicemia in animals, congestion of the duodenum is generally found. These facts and experiments would suggest that a substance has entered the blood, been excreted by the bile and on entering the duodenum has combined with or been split up by certain of the duodenal contents to form an intense irritant poison which has attacked the walls of the duodenum, setting up a violent inflammation.

Arkanzy suggests that traumatism to the abdomen may injure the mucosa of the upper part of the intestine more readily because of its relatively fixed position and thus afford a point of entrance for infection. MacCallum points out that due to the relative freedom from bacteria in the uppermost part of the intestine there might be a point of lowered resistance produced by the trauma and the streptococcus carried to it by the blood stream.

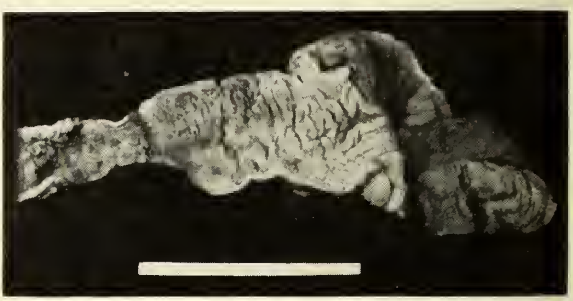

Fig. 1. Specimen of ileum removed at autopsy showing marked thickening.

Zoepffel considers that elderly men are prone to the disease by reason of diminished hydrochloric acid content of the gastric juice, which is therefore less bactericidal and allows injurious bacteria to reach the upper intestine.

Taylor and Lakin report a case of phlegmonous inflammation of the duodenum following the impaction of a fish bone. Fish bones, in their passage along the gastro-intestinal tract, may be arrested at any point and by perforating the mucosa carry infection to the deeper coats of the bowel.

The affected portion of the bowel shows marked thickening and stands out like a rigid tube. It has a velvety appearance and usually is a dark reddish color. There is often enlargement of the regional lymph nodes. There may be patches of fibrinous exudate on the peritoneal coat of the intestine. On section the mucous membrane is seen to be roughened and granular in character with irregular hemorrhagic areas. The submucous and muscularis coats also show considerable swelling, due to the purulent infiltration.

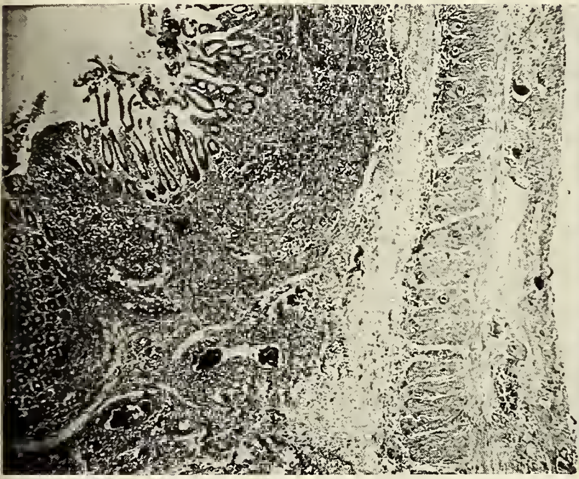

Fig. 2. Microscopic section of the wall of diseased ileum. Note the very decided thickening in the submucosa.

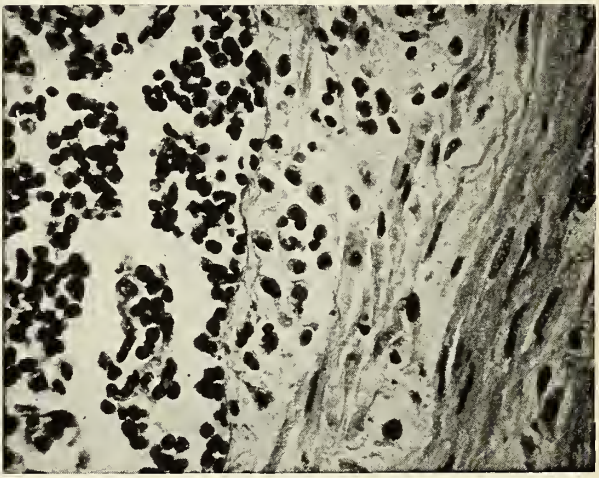

Fig. 3. Higher power section of the submucosa showing infiltration with lymphocytes, plasma cells and polymorphonuclear leukocytes.

The onset of the disease is characterized by cramplike abdominal pain which the patient often has difficulty in localizing. Nausea, vomiting, or both, may be present. The temperature is not usually high, and the pulse rate will vary with the severity of the case. As a rule there is an increased leukocyte count. Abdominal examination may show a slight distention, with tenderness and rigidity. These findings will naturally be dependent on the stage of the disease in which the patient is seen and the location of the lesion.

In considering the question of diagnosis I do not believe one could often form a more definite opinion than that he is dealing with an acute abdominal disorder that calls for immediate surgical intervention. Operation offers the only method of treatment that will benefit these patients. The operation of choice seems to be resection of the affected bowel with anastomosis to restore its continuity. This cannot always be carried out when the lesion is situated in the duodenum or upper jejunum. The prognosis is very poor and this can be improved only by early operation and recognition of the disease.

The first case I wish to present arose as a complication of scarlet fever and would be classed as secondary phlegmonous enteritis.

Case 1.—A five year old girl was admitted to the hospital on January 25, 1930, with a typical case of scarlet fever. Her temperature was 101, pulse 120, no complications. On examination it was noted that the abdomen was normal. Nothing unusual occurred until the night of January 30, when she complained of abdominal pain localizing in the umbilical region. This was followed by vomiting and a complaint of pain in the lower right quadrant of the abdomen. The next day she had four watery stools and developed extreme tenderness in the lower right abdomen. The leukocyte count was 45,000, temperature 101.6, and pulse 120. The urine was normal. X-ray of the chest was negative. Rectal examination revealed tenderness on the right side. I first saw the patient on the evening of January 31, and after examination made a diagnosis of acute appendicitis and advised immediate operation.

The abdomen was opened through a lower right rectus incision. The peritoneal cavity contained a small amount of turbid fluid. There was no odor. The appendix, cecum and terminal ileum were loosely adherent to one another by a yellowish fibrinous exudate. The serosa of the appendix, cecum and terminal ileum was very red, but I was struck by the thick tube-like character of the ileum for a distance of about 15 centimeters from the ileocecal valve. The mesenteric lymph nodes were markedly enlarged. I removed the appendix and closed the abdomen without drainage. The patient died February 2, from a general peritonitis.

At autopsy the intestines were dilated and covered with a fibrinous exudate, there being 200 c.c. of a thick, purulent material in the abdominal cavity. The gastro-intestinal tract was normal except in the region of the cecum. The terminal 15 centimeters of the ileum was markedly edematous, its wall being very much thickened and the mucosal surface roughened and granular in character with irregular hemorrhagic areas. This process ended abruptly at the ileocecal valve. The cecum and ascending colon showed congestion of the mucosa. The ileocecal group of glands were enlarged, measuring 1.5 to 3.5 centimeters in diameter. They were hard in consistency. The peritoneal surfaces were covered in places by fibrinous exudate, and the peritoneal surface over one of the glands showed a necrotic area which might have been the source of the peritonitis. There were a few ulcers of the Peyer's patches in the ileum above the diseased area.

Fig. 4. Shows Gram-positive diplococci in the wall of the intestine.

Microscopic section of the small intestine through the lesion revealed the wall to be markedly thickened. The surface layer of epithelium was absent and there was superficial ulceration of the mucosa. The glands were for the most part intact. The muscularis mucosa was destroyed in some areas by an acute and chronic inflammatory process and the submucosa decidedly thickened and infiltrated with polymorphonuclear leukocytes, lymphocytes and plasma cells. The muscularis and serosa were also diffusely and densely infiltrated with these cells. There was edema of all of the layers of the intestine but this was most pronounced in the submucosa, the phlegmonous inflammatory process being most marked in the submucosa and serosa. The thickness of these two layers was responsible to a large degree for the thickness of the intestine. The diffuse distribution of the inflammatory process and the absence of ulceration were characteristic of a phlegmonous inflammation. Gram stain of the lesion showed Gram-positive diplococci scattered throughout the wall. These were most numerous in the subepithelial tissue. In some areas the arrangement of the organism suggested short chains and it was thought that the etiologic organism in this case was the streptococcus.

Thinking the appendix might be playing a part in the process, I removed it, but of course this was unnecessary.

Looking back on this case and conceding the indication for a resection of the affected bowel, I do not believe it would have been feasible in the presence of the existing peritonitis. The next choice would have been an anastomosis between the ileum above the lesion and the ascending colon, but I am convinced that in this case the best choice would have been to have performed an enterostomy proximal to the lesion. This would have diverted the fecal current as well as a lateral anastomosis and is a much simpler procedure. If the patient survives the acute infection the bowel will undoubtedly heal and resection will not be necessary. The healing of such a lesion without resection is brought out in the following case.

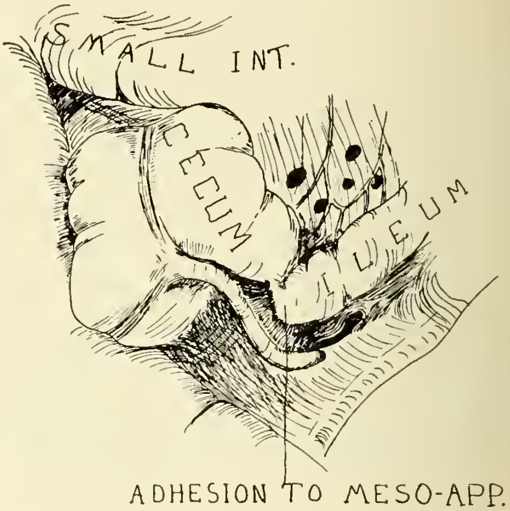

Fig. 5. Drawing showing partial obstruction of ileum and enlarged mesenteric lymph nodes.

Case 2.—Mr. N., a male aged 35, came to my office on December 20, 1930, complaining of pains in the lower abdomen. He stated that he was perfectly well until December 17, 1930. At this time he had some difficulty holding his urine. This was followed by intermittent abdominal pains which began in the lower right quadrant. The night before coming to the office he had a temperature of 101. The only thing of note in his past history was a complaint of lower abdominal distress occasionally after meals.

General examination was negative except for some slight tenderness and rigidity over the lower right quadrant of the abdomen. The urine was normal. The leukocyte count was 9,000; temperature normal. I told him I was not able to make a definite diagnosis but felt that he might have appendicitis. He was told to go home and remain quiet but to notify me if he had a recurrence of his pain. About 9 P. M. that night I was called to see him and he was again having cramplike abdominal pains. His temperature was 99.4°. Abdominal findings were the same as at the first examination.

I made a diagnosis of appendicitis and advised an operation. He finally entered the hospital the next evening. At this time his leukocytes were 15,000, pulse 80, temperature 99.

The next morning the abdomen was opened under spinal anesthesia. A right ractus incision was made. There was no excess fluid in the peritoneal cavity. The appendix was delivered and it did not appear acutely inflamed but a small knuckle of ileum was drawn into the wound with the appendix. There was a partial obstruction of the ileum due to its being adherent to the meso-appendix. The ileum for a distance of 10 to 12 centimeters was thickened, dark wine-red in color, with a glossy appearance to its serosa and had the tube-like characteristic of a bowel affected with a phlegmonous inflammation. The mesenteric lymph nodes were enlarged.

I relieved the ileum, removed the appendix and closed the abdomen without drainage. The pathological report on the appendix was negative. The patient made an uneventful recovery and states that since the operation his bowels are much more regular and that the occasional abdominal distress after eating has entirely disappeared.

This case also falls into the group of secondary phlegmonous enteritis as I believe his trouble was secondary to the partial intestinal obstruction which was found. Because of encountering the condition early in this case and also because of the presence of this very obvious intestinal obstruction I felt that by relieving the obstruction the exciting cause would be removed and the infection would subside. This is probably rather conservative treatment in the face of the bad results reported in the handling of this disease but I am sure there are different degrees of infection here as well as in other parts of the body and I believe we cannot say that any one method of treatment should be used in all cases.

In summarizing the facts gained from the study of this disease I wish to emphasize the comparative rarity of the condition and also the high mortality accompanying it. I believe a correct preoperative diagnosis of phlegmonous enteritis is very difficult but the recognition of an acute abdominal condition requiring immediate surgical intervention is of utmost importance. Resection of the affected bowel, when feasible, is recognized as the procedure of choice. When this is not possible anastomosis has been done between loops of bowel above and below the diseased area. In the very sick cases I believe simple enterostomy, if possible, proximal to the lesion should be the best method of treatment.

FRACTURES OF THE HIP*

A. R. Colvin, M.D.
Saint Paul

IN 1902 Whitman published a paper entitled, "A New Method of Treating Fractures of the Neck of the Femur." This method, now generally known as the abduction method, and also known as Whitman's method, is now recognized both in this country and in Europe as the standard method of treatment of these fractures.

The treatment of fractures in general consists in the reduction of the displaced fragments to as nearly the normal relationship as possible, and the retention of the apposed fragments until union has taken place.

Fig. 1. Intertrochanteric fracture of the neck of the fe mur.
Fig. 2. Result of treatment by traction of fracture shown in Figure 1.
Fig. 3. Intracapsular fracture of neck of femur.
Fig. 4. Result of treatment of fracture shown in Figure 3 by Whitman abduction method.

In fractures of the shaft of long bones, perfect apposition of the fragments is not always accomplished by non-operative treatment; nevertheless, union with good functional results is the rule. In fractures of the neck of the femur, union is rarely obtained unless perfect apposition is accomplished, and good function is never obtained unless union results. There is no longer any question as to whether union in these fractures ever takes place; the question is, rather, in what percentage does union take place? Since the advent of the abduction treatment, we can correctly say that at least hope has replaced despair, and optimism is justified. Notwithstanding this, percentages in success means likewise percentages of failure. But at any rate, we can say that by this standard method of treatment better results are obtained than by any other method of non-operative measures.

Perhaps by singling out certain items of experience a better understanding may be had why success and failure occur in a certain percentage of cases.

It is well at the outset to establish very clearly the types of fractures in this region. While there may be some theoretical reasoning regarding whether or not some part of the capsule is included in the fracture line, still for practical purposes, the old classification of extra and intracapsular fracture of the neck of the femur is important. We may say that the nearer the fracture to the cartilage covered head, the greater danger of non-union; or, in other words, the nearer the fracture to the trochanters, the far greater likelihood of union, until we come to the intertrochanteric and peritrochanteric regions, when union practically always occurs and greater latitude in manner of retention is allowed.

With the intracapsular fracture, the standard method of treatment is the abduction treatment, which consists of reduction of displacement, apposition of fragments and retention in apposition until union takes place—and after this a prolonged period of protection. Statistically the percentage of union with this treatment may be placed at about 65 per cent. Perhaps those who report as high as 80 or 90 per cent have not had a sufficient number in which to meet the inevitable failures which would reduce their high percentages. This unfortunately has been the experience which has given to me a becoming sense of humility and a recognition of the true state of affairs.

---

*Presented before the annual meeting of the Minnesota State Medical Association, Minneapolis, May 6, 1931.

It would hardly be possible in the time allotted this subject to go into details of treatment. I hope to show rather on the screen what results can be obtained and where the results have not been good to try and indicate why.

Fig. 9. Intracapsular fracture of neck of femur.
Fig. 10. Reduction obtained in case shown in Figure 9 by Whitman method.
Fig. 11. Atrophy of neck in case shown in Figures 9 and 10.
Fig. 12. Final result in case shown in Figures 9 and 10, support obtained by lesser trochanter impinging on head. Functional result—poor.

In our experience the failure of union has been due to absorption of the neck, and, except in one case, not to the condition of the head. In this one case, the patient had been afflicted with poliomyelitis in early life, and, his subcapital fracture not uniting, a reconstruction was undertaken. The head was found to be yellow and soft—perhaps necrotic would best describe the condition.

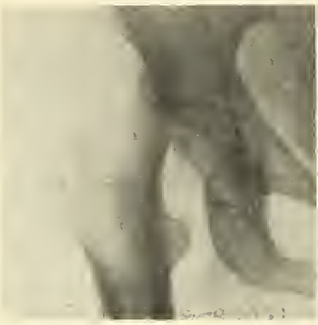
There seems to be some doubt whether the atrophy of the neck is due to some inherent cause in the neck itself, or whether it atrophies secondarily to lack of sufficient osteogenetic properties and non-union in the head. At any rate this atrophy of the neck occurs quite early in some cases. Schmorl says it may become evident in a few weeks. Lorenz puts it very clearly when he says one must not blame the unfavorable anatomical conditions alone for the bad results in fractures of the neck of the femur, and only do so when incomplete reduction and faulty retention can be excluded. Insufficient protection later must also be excluded.

It is not sufficient to take a radiograph before and after reduction, but to take them also during the progress of the case and correct a possible displacement.

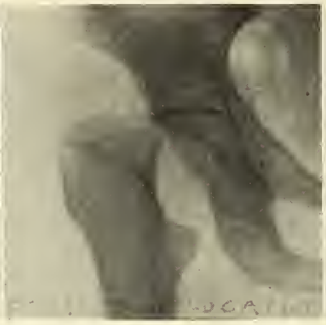
What about the cases in which we do not get union after standard treatment? Briefly, there are various methods of helping these patients, depending upon the exact condition present:

1. Manipulation and reapplication of the cast.
2. Exposing the fracture, freshening the ends of the fragments and again treating with abduction and a cast.
3. Adding to the above a bone peg or transplant.
4. Whitman's reconstruction operation.
5. Backett's reconstruction.
6. Lorenz forking operation.

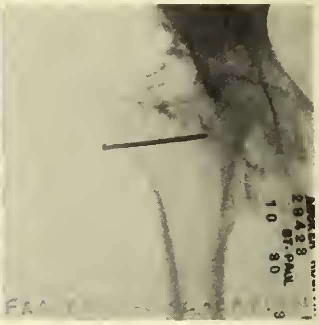
Some of these operations, Whitman's reconstruction, for instance, may be performed as a primary procedure, because in the judgment of the surgeon there is no hope for a functional result in non-operative treatment.



13



14



15

Fig. 13. Fracture dislocation of intracapsular fracture of neck of femur, part of head remaining in acetabulum.

Fig. 14. Case shown in Figure 13 after manipulation, part of head remaining on dorsum of ilium, the other half remaining in acetabulum.

Fig. 15. The result of Whitman's reconstruction operation in case shown in Figures 13 and 14. Functional result—patient walks with a cane.

Before resorting to operative treatment, however, it is well to consider the following facts:

1. Twenty per cent of all of those afflicted with fracture of the neck of the femur die in the first month.
2. Failure in abduction treatment can be followed by various operations later on.
3. Success in bone transplant (pegging) results in selected cases.
4. In 20 per cent of all well treated cases bony union fails and pseudarthrosis occurs.
5. Twenty per cent of all pseudarthroses give comparatively good functional results, due to fibrous union and compensatory support.
6. In numerous cases fibrous union finally become osseous after a greatly prolonged treatment. Perhaps we may use the term delayed union here.

FRACTURE OF THE HUMERUS*

Henry W. Meyerding, M.D.
Rochester, Minnesota

THE automobile has produced an unusual number of serious accidents in which the saving of life is the first consideration, the saving of the injured extremity with good functional result second. The physician who is first to be called in these emergencies must be prepared to meet the immediate effects of trauma and to act to prevent complications. Shock, pain, hemorrhage, injury to nerves, atrophy, stiffness of joints, even infections, frequently can be prevented by prompt modern treatment. Aided by exact diagnosis as to type of fracture, which the roentgenogram permits, results are better and the period of disability is shortened. The value of traction splints was clearly demonstrated in the World War, and is today recognized and recommended almost universally. The simplicity of construction, ease and rapidity of application, and low cost, further make them desirable as standard appliances which hospitals, ambulances, and practitioners should have available.

I favor conservative treatment of fractures, and believe that excellent results are obtained by reduction and fixation when applied before swelling and edema occur. Nevertheless, I do not hesitate to perform open reduction and internal fixation when conservative measures fail, and when I encounter certain fractures which in my experience require these measures. Results of both methods of treatment vary greatly in any given type of fracture, depending not only on the methods employed, and on the skill and experience of the physician, but also on the health, cooperation and environment of the patient. My observations lead me to believe that failure of open operation is mainly due to infection, although both inadequate internal and external fixation play a part. The surgical expert who treats fractures in the modern hospital observes a minimal amount of infection and practically no mortality. He may feel that his excellent anatomic and functional results warrant him in operating for fractures as a routine. The general physician who skillfully carries out conservative or closed treatment is following what is for him a much safer procedure, and his results, in uncomplicated cases, may equal or exceed those of the physician who performs an open operation only occasionally. The best results should come from the experienced fracture teams, surrounded by the most modern of facilities, with patients under constant observation and control.

As an emergency device for fractures of the humerus the Thomas-Murray splint is excellent. Having inspected and palpated the arms to compare bony landmarks, noted any interference with nerve and blood supply, and dressed any abrasions, the ring is slipped up the arm and traction applied by means of adhesive tape or a temporary cuff. The traction splint provides continuous pull, which tends to correct deformity, to prevent injury to the soft tissues and consequently to lessen pain and shock. In a few moments after the physician's arrival the patient is ready to be transported comfortably to home or hospital. Compound fractures are likely to be infected by rubbing and attempts at cleaning applied at the scene of accident. It is better to employ only a sterile gauze pad as first aid; if necessary, later, thorough debridement can be carried out and antitetanic serum administered. The exact injury to soft parts, hematoma, paralysis, and evidence of interference with circulation must be noted. Roentgenograms on which are recorded the date they were made, whether they are front or side view, and the arm involved should complete the record even though reduction has been performed with the aid of the fluoroscope. Later embarrassment and worry are minimized when such records are available, for with the automobile age came also the medicolegal, insurance and compensation age. Following treatment, roentgenograms at intervals of two to three weeks are indicated to determine whether position is satisfactory. The physician should bear in mind, however, that he is concerned with restoring form and function primarily, not anatomic alignment. The roentgenogram has focused attention on perfect reposition, and in attempts to obtain it I feel that much harm sometimes has resulted to soft parts. In deciding on treatment, age of the patient, his physical condition, the type of injury he has sustained, and his economic circumstances should receive consideration. The public expects perfect anatomic and functional results in the shortest possible time. Various agencies interested in the economic phases of treatment and disability demand details of treatment, prognosis, and progress. The wise practitioner will seek counsel early when confronted by the unusually serious and complicated fractures.

---

*From the Section on Orthopedic Surgery, The Mayo Clinic, Rochester, Minnesota. Read before the Minnesota State Medical Association, Minneapolis, May 6, 1931.

A factor in the success of any treatment involving fractures of the humerus is the anatomic sense of the physician. Thus, in fractures of the anatomic neck of the humerus the rounded head, facing upward, inward and slightly backward from the shaft, may slip about like a saucer. Fracture of the greater tuberosity of the humerus, by virtue of the pull of the supraspinatus muscle, makes reduction difficult unless traction is made in the direction of the fractured part. The action of the deltoid muscle in fractures above and below its insertion affects the position of the proximal fragment. The teres major, latissimus dorsi and pectoralis major muscles pull the lower fragment forward and inward. The long head of the biceps muscle may be torn or may lie between the fragments. Although the humerus may be broken by direct or by indirect violence, it, more than any other bone, fractures from muscular action. The radial (musculospiral) nerve lies in a groove in close proximity to the humerus as it winds its way downward. It may be injured by sharp edges of bone at the time of the accident, during manipulation, or by pressure of callus, producing wrist drop.

The humerus is one of the most common sites of nonunion. In fractures of its lower third supination forces the lower fragment outward, and tends to cause flexion due to the muscle pull of pronation. When the edge of the bone is sharp and hemorrhage lifts up the periosteum, tension may be increased, forcing the radial nerve against the bone and causing paralysis. Pronation permits the distal fragment to line up more easily, and splinting, the action of the triceps muscle and acute flexion permit retention of fragments. The internal and external condyles lie forward of the axis of the humerus. The carrying angle bends the extended forearm away from the body at an angle ranging between 162° and 178°. The coronoid fossa in front, and the olecranon fossa behind, lie between the condyles, and are necessary to permit full movement of the elbow. Thus, callus, fragments of bone, or malunion, which interfere with the normal shape of the structures named, cause limitation of motion. When supracondylar fractures are improperly reduced, the end of the distal fragment is pulled backward, and the proximal end forward and downward to compress blood vessels and nerves about the antecubital space. Hemorrhage becomes increasingly dangerous as the site of fracture comes closer to the elbow. Therefore, the greatest care is required in preventing intrinsic and extrinsic pressure, or else Volkmann's ischemic paralysis results.

Fractures of the humerus are usually roughly divided into those of the upper end, the shaft and the lower end. Like fractures of other bones, those of the humerus may be simple or compound, or pathologic or spontaneous. Table 1 is a classified list of fractures of the humerus.

TABLE 1

FRACTURES OF THE HUMERUS

- Upper end
    - Fracture-dislocation of the shoulder
    - Of the anatomic neck
    - Of the surgical neck
    - Of the tuberosities
    - Epiphyseal separation
- Shaft
    - Transverse
    - Oblique
    - Comminuted
- Lower end
    - Supracondylar
    - Transverse dicondylar
    - Of the external condyle
    - Of the internal condyle
    - "T" or "Y" fractures into the joint
    - Epicondylar, internal and external
    - Epiphyseal separation

In a series of 114 recently studied injuries involving the humerus, there were twenty-four dislocations of the shoulder, ten of which were complicated by fracture in the upper third of the humerus; twenty-one fractures without dislocation of the surgical neck; one fracture of the anatomic neck; one comminuted fracture of the head; one epiphyseal separation; two fractures of the greater tuberosity; twelve fractures of the shaft; forty-one fractures of the lower third; three fractures of the lower third, with dislocation of the elbow, and eight dislocations of the elbow. Some of the fracture dislocations of the shoulder were of weeks' standing. Sir Robert

Jones, in his presidential address to the International Society of Orthopedic Surgeons at Paris, in October, 1930, spoke as follows:

"Some years ago I was engaged as a witness of a medicolegal case. One of the issues referred to the method of reduction which should be employed in a case of dislocation of the head of the humerus with fracture of the surgical neck. Many distinguished surgeons in 1906 did not know of such an injury. They were astonished to hear that fifty years before the Christian era, Pasicrates, in describing the injury, stated that he preferred to reduce the dislocation and then to allow union of the humerus. Aristion, on the contrary, endeavored to so arrange traction that it would act on both head and shaft simultaneously. Heliodorus supported the contention of Pasicrates. It is of profound interest to realize that in olden times, just as today, schools existed, one in favor of immediate reduction and the other in favor of allowing the shaft to unite before dealing with the displaced humeral head: and so it is always."

In fracture-dislocation of the upper part of the humerus, the dislocation is sometimes unrecognized for months, resulting in permanent partial disability of the extremity, in spite of the most expert reconstructive surgery. Inspection, palpation, and roentgenograms to include both shoulders should be made whenever doubt exists. I have seen and operated on patients weeks after injury, in whom dislocation had not been recognized, although roentgenograms had been taken and treatment had been given for fracture. An attempt to reduce the dislocation should be made as soon as possible, and always with anesthesia. By abduction traction of the arm, and pressure in the axilla with foot or hand, most dislocations are reduced. If one waits for swelling to subside or union to take place, adhesions and scar tissue may fix the head so that great force is necessary, and injury to blood vessels and nerves about the axilla may result. I have found that careful dissection with the knife is required in cases of long standing. Every effort should be made to save the head and replace it in the glenoid cavity, but at times this cannot be accomplished. Once the dislocation is reduced, the treatment is carried out as for fractures of the upper part of the humerus. If internal fixation by Lane plates, bone screws, or Parham bands is employed, active motion can be started immediately, and the functional result will be excellent. This is a type of injury in which early consultation is urged, especially when great swelling, injury to nerves, or infection exists.

Fractures of the anatomic neck are rare, usually are of the impacted variety, and occur in elderly patients. If position is fair, a sling and rest for two or three weeks is ample. When the head is loose and displaced, traction, after manipulation or open reduction, and early movement, are indicated. In cases of long standing, the head, which is loose and is the cause of pain, should be excised. Recumbency in the aged is avoided, and active movement, assisted by the physician, is urged. Forceful movements are avoided as being painful and harmful, but if it is necessary to break up adhesions, this must be done with the greatest care and under anesthesia.

The common fractures of the surgical neck include those that are below the tuberosities, involving the proximal fourth of the shaft. On inspection it may be mistaken for axillary dislocation. The proximal fragment is pulled upward and forward, the lower fragment is pulled forward and inward, and traction is made in the direction in which the proximal end points. The position of choice in treatment is abduction 90°, external rotation 90°, with the elbow at 90°, and the humerus forward of the sagittal plane 30° to 45°. Traction following reduction is maintained in recumbency by any of the abduction splints, such as the aeroplane splint, the Cramer wire splint, or by spica casts. Active motion of the hand and elbow is begun at once. Besides being most useful for maintaining reduction, this position prevents swelling and edema, and the early movement inhibits atrophy and stiffness. Should impaction be present, and the fragments in good position, a sling and plaster of paris shoulder cap are sufficient. Since many of these fractures occur to patients who have severe bodily injuries, recumbency is often preferable to ambulatory treatment. With overhead suspension of the forearm, and lateral traction applied above the elbow or through the olecranon, by means of a rustless steel pin, the physician has more certain control of the patient. Too often bandages and splints lose their efficiency through interference by relatives and friends. The physician is held responsible, irrespective of what the patient may do. Usually fixation for four to six weeks is required; movement of the shoulder is allowed at the end of a month, but movement of the elbow and hand is encouraged from the beginning.

Fracture of the greater tuberosity is frequently complicated by subglenoid or anterior dislocation, and results from direct violence or from shearing force. Treatment is directed toward bringing the arm to a position so that the fragments which are pulled upward and backward may be replaced. This is accomplished by abduction, external rotation, and pressure. When displacement is not great, good results may be obtained by simply a sling. Irreducible fractures are exposed through the posterior Kocher incision, fastened by suture or by beef bone screws, and early movement begun. Abduction external rotation splints are recommended. The treatment of epiphyseal separation is essentially the same.

Fracture of the shaft by direct lateral force is usually transverse. Indirect transmission of force may cause oblique or spiral fractures, and many of the cases of comminution result from extreme muscular effort. The results are usually good, although the shaft is a common site of nonunion, and injury to the radial nerve is not unusual. The presence of wrist drop immediately after injury demands expert advice as to operation. Late paralysis in the region of distribution of the radial nerve is due to pressure of callus, and may disappear in the course of a few weeks, as hardening of callus and shrinking take place. Inadequate fixation, interposition of muscle, and overstretching are factors in the production of nonunion. The commonly used short compression splints and sling are inadequate and lead to many of the imperfect results. They permit too much movement of the fracture, and the weight of the arm, unless constantly supported, tends to produce faulty alignment and to favor edema. Elevation of the forearm in recumbency or supporting it on an abduction splint prevents edema and permits movement of elbow and hand. Too often the apparatus applied extends from the wrist to the site of the fracture or just above it, and the slightest movement of the forearm is transmitted to the fracture. When good apposition of transverse fractures is obtained, a well fitted shoulder spica, extending well onto the forearm, is satisfactory and safe. If there has been great injury to the soft structures, hemorrhage or edema, recumbency is preferred. In overriding and spiral fractures, manipulation or traction may fail to bring about approximation, and open operation may reveal interposition of muscle. Rough handling of these fractures should be avoided, and the physician must be sure that the nerve is intact before treatment, for, if paralysis occurs, he may be held responsible.

Fracture of the lower end of the humerus, in spite of expert care, may end in disastrous complications. The physician, to be successful, must know the exact extent of the injury. Is it an intra-articular or an extra-articular fracture? How do the two arms compare as to carrying angle, swelling, length, movement, deformity, circulation? Roentgenograms, following careful clinical observation, should be made in two planes. If the joint is involved, hemorrhage and fixation tend to produce stiffness, or even ankylosis. Loss of carrying angle, injury to nerves and that dreaded sequel, Volkmann's ischemic contracture, should make the physician regard seriously these fractures of the lower end of the humerus and be guarded in his prognosis. After reduction the position of choice is flexion, for it favors good function in bending the arm toward the body, and aids in most instances to retain the fragments in good position. If marked swelling exists, reduction is deferred until elevation of the arm reduces it. In no case is it wise to force flexion, with hemorrhage and edema threatening to impair circulation. On the other hand, the pulse, color, and temperature should always be observed, and if hematoma or the position of the bone causes interference, the clot is removed and the position of the fracture is changed by open reduction. Watchful waiting, if gangrene or ischemic paralysis threaten, is contra-indicated; a few hours of waiting may mean loss of the usefulness of the limb. The situation of the fracture in 128 cases of ischemic contracture is given in Table 2.

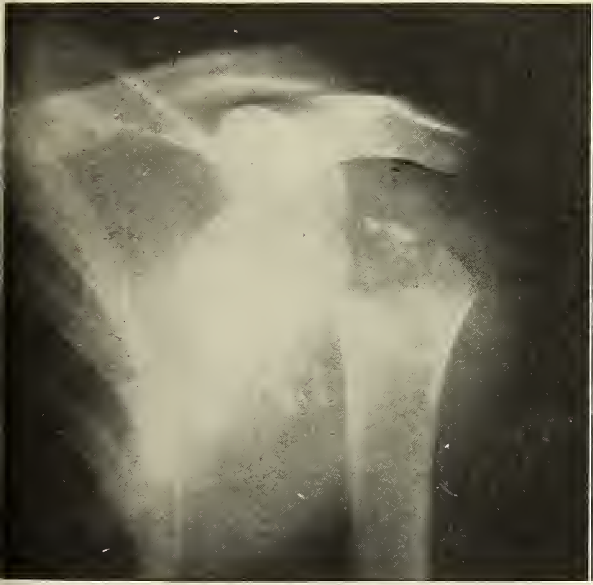

Fig. 1 (Case 1). Fracture-dislocation of left shoulder.

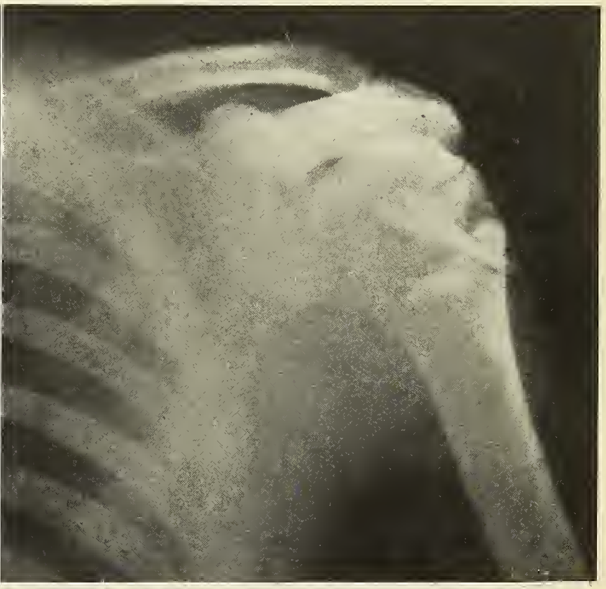

Fig. 2 (Case 1). Fracture-dislocation of left shoulder, reduced.

The most common of the fractures of the lower end of the humerus are supracondylar. They are seen frequently in children, resulting from falls on the hand or elbow with the arm extended; the lower fragment is carried backward, he upper fragment, forward, and the periosteum of the humerus becomes stripped up for several nches. In adults who fall on the stiff, flexed arm, the lower end is pulled forward. Muscular pull maintains displacement; hemorrhage, often severe, increases intrinsic pressure, and if flexion without proper reduction is maintained, or marked swelling is present before manipulation, he stage is set for ischemic contracture. The fracture must be reduced, and the sooner the better. Whenever possible a reliable observer should be engaged for the first forty-eight hours o see that circulation is adequate. Too often stiffness, sloughs from pressure, and contractures are present on the physician's second visit, and nquiry discloses that the patient has suffered great pain, which was relieved by drugs. The cold, blue, swollen, wet hand was unnoticed; he injury has been done, and now months of reatment, with uncertain prognosis, begins. Let t be remembered that Volkmann's ischemic contracture may occur in cases in which treatment has not been given. By hyperextension, traction with manipulation of the lower fragment into position, and then acute flexion, the fracture is reduced and maintained by muscular pull and by the splinting action of the triceps muscle. Supination tightens the pronator muscles, and their pull tends to force the upper end of the lower fragment outward, and also flex the elbow. This may cause pressure against the radial nerve, and paralysis may result; pronation is therefore advisable, for it makes easier reduction and retention and avoids injury to nerves. Adhesive plaster passed over the shoulder and over the forearm is frequently used to maintain flexion, or the Jones cuff suspended from the neck. They permit inspection, palpation, and loosening if necessary. Light plaster of paris moulds cause less pressure and are perhaps preferable. Early, active motion is essential in preventing stiffness.

Transverse dicondylar fractures involving the joint require similar care. Fracture of the condyles and capitellum, if not displaced, require immobilization in splints or plaster for two to four weeks. When satisfactory reduction by manipulation fails, open operation and suture, or a bone screw, are indicated. The ulnar nerve may be injured and early suture or late transplantation may be advisable. The arm is placed in the position at which the fragment seems to hold its place, and a well fitted splint or cast is applied and is allowed to stay in place for two or three weeks. At the end of this time, gentle, active movement aided by the physician, with the splint off, results in restoration of movement.

"T" and "Y" fractures, and intercondylar and multiple fractures resulting from falls on the elbow, often drive the olecranon up between the condyles and split the humerus. Moulding and traction are indicated, with flexion. Skeletal traction, with a rustless steel pin thrust through the olecranon, and abduction casts or splints, give better results than if the arm is held at the side. Open reduction, with fixation of fragments, is only for the expert, working with the most careful technic. The earlier motion can be started, the better the motion which will result. Epicondyles, if displaced, may be sutured or removed. Epiphyseal separations may be reduced by manipulation, and traction may be used if flexion fails to maintain them in position. Immobilization is maintained for three or four weeks.

Nonunion of the humerus requires the care of an expert bone surgeon who is accustomed to a technic which involves many special instruments and which exacts the utmost in aseptic precautions. After exposure, the ends are freshened or excised; the medullary cavity is drilled out, and the ends are brought together. A properly shaped graft is removed from the tibia and is applied as a massive inlay, held by bone screws. Cancellous bone, curetted from the tibia, is then forced about and between the freshened ends. The periosteum and the muscles are then pulled snugly over the region of the graft. Finally, the skin is closed without drainage. A plaster spica cast to fix the humerus and support the forearm is used until union is firm.

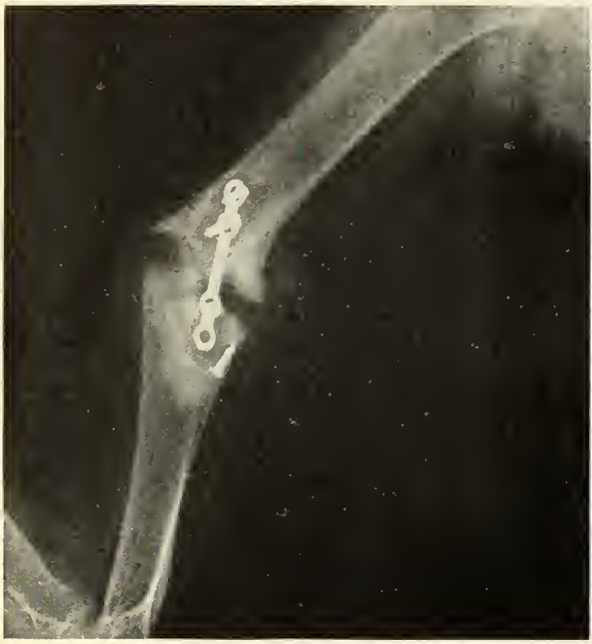

Fig. 3 (Case 2). Nonunion of right humerus, with loose Lane plate and pseudo-arthrosis.

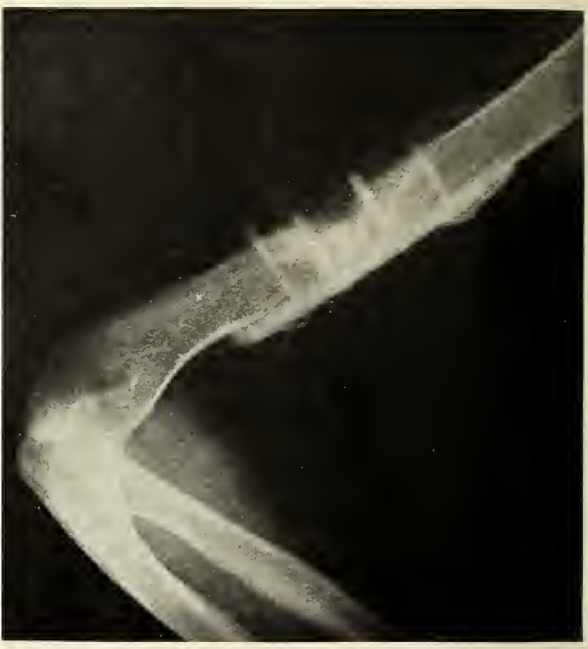

Fig. 4 (Case 2). Autogenous bone graft held in place by beef-bone screws six months after operation for nonunion of the humerus.

REPORT OF CASES

Case 1.—A man, aged twenty-five years, was injured in an automobile accident and was taken to the hospital unconscious. Emergency treatment was given, and roentgenograms were taken, which gave evidence of a split in the head of the humerus, and dislocation. Traction was applied, and four days later, when his general condition was satisfactory, he was referred to the clinic. Open reduction and internal fixation, by means of three beef-bone screws, held the fragments in anatomic position. He wore an abduction cast three weeks, at the end of which time he returned home, able to abduct his arm 60°. Thirteen months following the accident he reported that function of the shoulder and arm was normal (Figs. 1 and 2).

Case 2.—A woman, aged twenty years, sustained a compound fracture of the middle third of the humerus twenty-two months previous to her visit to the clinic. After fixation in splints for two months she had been operated on for delayed union; a "bone graft and four hole steel plate" were applied. Nonunion and drainage resulted; the plate became loose and she came for an opinion as to the value of further operation. The Wassermann test was negative. The Lane plate and screws were removed; the pseudo-arthrosis was excised, and an autogenous bone graft, held by four beef-bone screws, was applied. External fixation consisted of an abduction spica cast extending to the and. The patient left the hospital twenty-four days fter operation, and the cast was removed at the end f three months, when sound, bony union and good unction existed (Figs. 3 and 4).

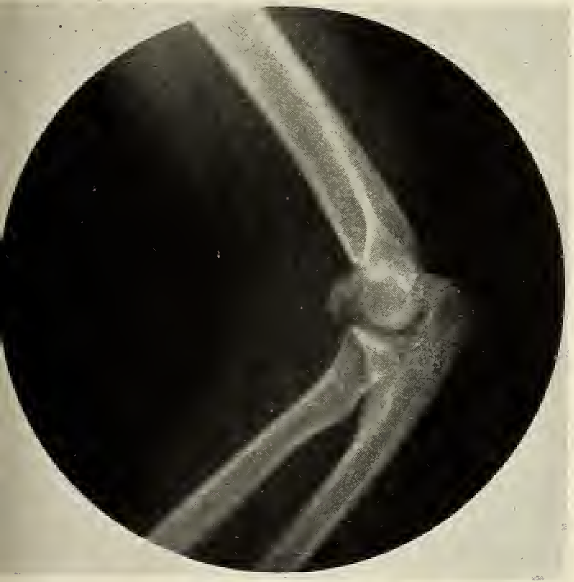

Fig. 5 (Case 3). Lateral view of fracture of capitellum of the humerus.

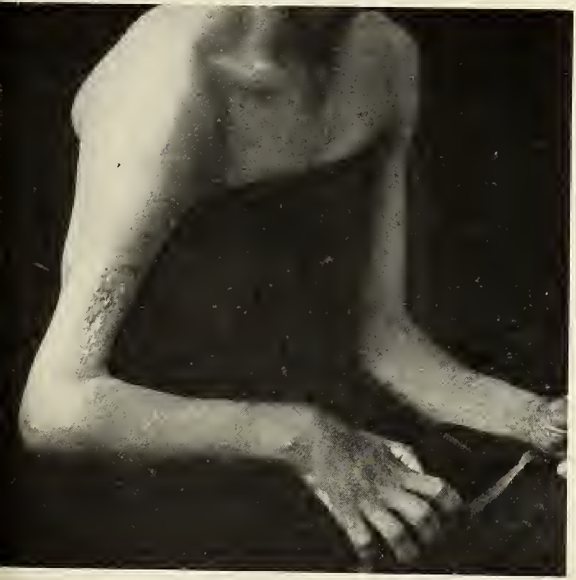

Fig. 6 (Case 4). Volkmann's ischemic contracture and scars rom slough of skin.

Case 3.—A nurse, aged nineteen years, fell, injuring er elbow. Roentgenograms were taken immediately, nd a diagnosis of fracture of the capitellum was made. It was thought that an open operation would be necessary, but manipulation under anesthesia was first tried and the fracture was easily reduced. The patient wore a sling, and in two weeks had practically full flexion and extension (Fig. 5).

Case 4.—A boy, aged nineteen years, sustained a supracondylar fracture of the right humerus six years previous to his visit to the clinic. He had been treated by manipulation, flexion, and a wire splint. The next day, the hand had been black and swollen, and his physician had taken off the dressing for an hour; then he had reapplied the same splint, and had left it on two weeks. A hand splint had then been applied and worn for a month, but in the distribution of the radial nerve paralysis had occurred and numbness had been present. A slough from pressure had appeared on removal of the first dressing, and the marks of it show clearly in Figure 6. Stiffness of the elbow, wrist, fingers and hand had resulted, which had persisted in

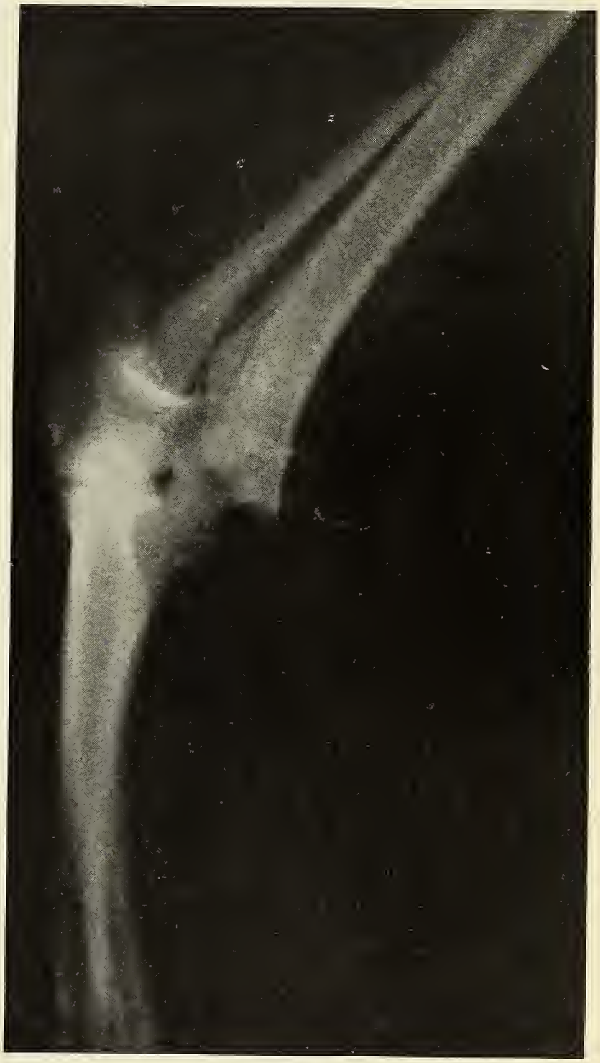

Fig. 7 (Case 5). Comminuted fracture of lower end of humerus.

spite of any treatment. Osteotomy of the humerus for malunion and tendon transplantation for injury to the radial nerve was performed. The patient left the hospital on the sixteenth day. Five months later his physician reported good function.

Case 5.—A woman, aged thirty-one years, was thrown from an automobile, striking on the right elbow. She was taken to the hospital and roentgenograms gave evidence of a comminuted fracture of the elbow of the "T" type, with a split of several inches in the humerus. Open reduction was immediately performed, and traction was made by wire through the olecranon. The arm was supported on the abduction splint, and she left the hospital on the eleventh day. The splint was taken off at the end of four weeks, a sling was used, and physical therapy was begun. She has returned to her usual occupation, has good flexion, with motion of 70°, and is still improving after nine months (Fig. 7).

SUMMARY

Fractures and dislocations of the humerus should be immediately reduced and retained by apparatus which permits motion of joints and avoids edema and pain. Abduction traction splints are most serviceable, easily made, economical, and should always be available. The condition of the patient, in this age of serious accidents, may require measures to save his life first, but emergency traction by simple means during transportation and after are best. A knowledge of anatomy is indispensable, for muscular pull, conformation of bone and distribution of nerves must be taken into consideration. The conservative methods are favored, but when they fail early operation is to be resorted to by one accustomed to it. Active motion is to be encouraged and gently assisted by the physician, when, in his judgment, it is safe. Passive and forceful movement of stiff, painful joints is harmful. Fractures of the surgical neck and upper end of the humerus are not infrequently complicated by dislocation. Roentgenologic examination before reduction and in the course of treatment is urged. One should always be on guard for injured circulation, especially in fractures about the elbow. Flexion, when marked swelling occurs, should be avoided. Volkmann's ischemic contracture may occur without use of splints or casts.

FRACTURES OF THE ANKLE JOINT*

J. S. Holbrook, M.D.
Mankato, Minnesota

In this necessarily brief discussion of fractures of the ankle, a few principles of treatment will be mentioned in the hope that they will be of help in the care of these cases.

The ankle has a hinge-like motion, and that only, normally. The very strong internal and external lateral ligaments hold the foot very firmly. The tibiofibular ligament holds the bones very stoutly together, and thus prevents lateral motion between them and the astragalus. There is a very strong attachment of the fibula to the astragalus by ligaments, which are so firmly attached that the astragalus remains attached to the fibula and is displaced with it in severe ankle injuries. Dickson[2] says that this is the key to the whole situation.

In the ankle joint the weight of the body is carried by the small articular surface between tibia and astragalus, when the flat surface of the former glides over the rounded convex surface of the latter. This near mortice joint is so firmly held by the capsule and its thickened portions—the internal and external lateral ligaments—that there is practically no lateral motion. The lateral motion which we get in this neighborhood is between the os calcis and the astragalus.

Up to about 200 years ago, the injuries of the ankle were considered dislocations, and treated as such. However, Pott and Dupuytren began to teach that these dislocations were often accompanied by fractures. These men did some wonderful work, considering that their diagnoses had to be made from the appearance of the ankle and examination by touch and manipulation. For the past thirty-five years the roentgen ray has been increasingly used, and the films have become so uniformly good that the pendulum has swung so far that the injuries about the ankle joint now are estimated by the amount of fracture.

Cotton and Berg[1] brought out the point that these injuries are really dislocations, often accompanied by fractures, as taught by Pott and Dupuytren about 200 years ago, and that they should be treated with this idea in mind. They classify the ankle injuries as:

1. Outward dislocation—Pott's Fracture.
2. Inward dislocation—reverse Pott's fracture.
3. Backward dislocation—Cotton's Fracture.
4. Upward and forward dislocation.

In the first class, the outward dislocation, the foot is displaced outward, the internal malleolus is torn off, and the fibula fractured about two inches above its lower end. Reduction of this fracture by forcing the foot inward will bring the fractured bones into proper position. One cannot over-correct it.

In the second class, the inward dislocation carries the foot inward and upward, and the external malleolus downward. The treatment consists of forcing the foot downward and outward, pushing it into place and maintaining it in this position.

In the third class, the backward dislocation of the foot with a fragment torn from the posterior part of the tibia is reduced by pulling the foot forward, and fixing it in dorsal flexion.

In the fourth class, which consists of a crushed lower end of the tibia with upward displacement, the fibula is seldom fractured. The upward thrust shortens the shaft of the tibia one-fourth to one-half of an inch, the amount depending upon the severity of the fall. There is a spreading of the ankle joint due to rupture of the tibiofibular ligaments. There is so much swelling and deformity that the diagnosis should be made by the X-ray. The treatment consists in correcting the displacement under an anesthetic, molding the fragments of the comminuted tibia into place, and extending the foot by use of a Sinclair skate, or otherwise; and maintaining corrected position much longer than external and internal dislocation-fracture. If reduction of fragments cannot be maintained, open reduction and nailing may be necessary.

I here will report the case of a boy, aged seventeen, who slid off the roof of a barn, landing on his feet. He claims that he fell 30 or 40 feet. He suffered a fracture of the left os calcis, and a comminuted fracture of the lower end of the right tibia, with the usual upward thrust, and shortening of one-third of an inch. Two attempts were made to maintain reduction in this case, but it could not be done until the fragments were nailed onto the shaft. Quite a large piece of the articular surface was found entirely separated and was removed. This boy made a good recovery, having almost normal motion in both feet.

---

*Read before the Minnesota State Medical Association, Minneapolis, May 6, 1931.

The second hint in treatment comes from Edward Holman Skinner of Kansas City,[4] who has devised a mean of estimating the amount of displacement and probable functional disability which is likely to result from a given ankle fracture. The restoration of the astragalus to its normal relation to the tibia is the result to be sought. The weight bearing line of the tibia should pass directly through and bisect the articular surface of the astragalus. A line so drawn on a film will show the amount of displacement of the astragalus.

Skinner remarks "that even though the apposition of the fragments may not be perfect, the functioning result will be satisfactory, if the weight bearing line is restored to normal alignment. Apposition of the fragments may be sacrificed to the restoration of function."

The third suggestion for treatment is by Fraser B. Gurd,[3] who tells of the use of the pillow splint at Montreal General Hospital. This splint has been used in that hospital for twenty-five years with gratifying results in fractures of the ankle. In his paper he says: "In our Clinic, following reduction, the leg is placed in a pillow splint. For this purpose a moderately deeply feathered pillow is required, covered with a pillow-slip made of some strong material. The leg is placed upon the center of the pillow, with the latter projecting about 6 inches beyond the heel. The pillow is made to surround the leg, commencing about or, better, above the knee, and firmly secured by means of safety pins placed in the long axis of the limb. Working from above downward toward the ankle joint, safety pins are placed in this way at short intervals. In this manner, lateral and circular compression is exerted. This is of value in limiting the swelling, and forcing, by gradual pressure, if reduction has been incomplete, displaced fragments into position. This is particularly useful in overcoming separation of the tibia from the fibula."

The foot is held by the pillow in dorsal flexion. The advantage of the pillow splint is that there is no danger of ischemic paralysis. It can readily be opened up for observation, and re-adjustment may be made several times the first few days. No extra board splints are put within the pillow case. X-ray should be taken through the pillow. The foot remains in this splint until the swelling is gone, when a circular plaster of Paris bandage is applied without employing padding. This remains on for ten days. It is then bisected, the posterior part being retained for a splint. Light massage and diathermy, baking, and active motion are employed for six days. Then another cast is applied with a heel, one inch thick, strapped on.

Gurd says, "By this method many return to work a week or two after the injury." He claims more perfect results than by other methods.

The fourth method of treatment of fractures is that advocated by Böhler. I understand that he always uses a local anesthetic, consisting of 10 to 20 c.c. of a 2 per cent novocain solution, injected directly into the break. I have used this with satisfactory results on many occasions.

His method of taking care of fractured ankle is to have the patient lie with his injured leg hanging over the end of a table. He molds the fragments into place, and applies a posterior splint of plaster of Paris, molded about the malleoi, and then a circular plaster of Paris bandage over that. The leg is not shaved, and there is no padding used, the plaster being put directly on the skin. After this has set slightly, a piece of strap iron, one-eighth of an inch thick and three-fourths of an inch wide, is bent so as to project one-half inch below the heel, and extend up the sides of the leg internally and externally. At the upper ends are cross-pieces to aid in holding the iron firmly. This is incorporated in the cast by several thicknesses of plaster bandage. In many cases the patient is encouraged to walk within two hours after the accident.

I have not used this method in an ankle, but did in a case of fracture of the tibia in its middle third. The patient did very well. While at the hospital he walked around the bed many times, but when he returned home, after three days, the family doctor and the patient's friends persuaded him that it was a very risky thing to do—so he used crutches. However, he immediately went back to his work as a stock-buyer, and lost but four days work, after the leg was put into a cast. He was very much pleased with the result, and felt that his disability had been greatly shortened by allowing him to get about.

The method carried out by Lorenz Böhler allows the patient to continue his occupation and saves him much time and expense. He claims for it that there is but little swelling, and the patient is very comfortable.

To recapitulate:

1. Always make free use of the X-ray before and after reduction, taking antero-posterior and lateral plates.
2. An anesthetic should always be used at the time of reduction.
3. Consider ankle injuries as dislocations with possible fractures.
4. Reduce the dislocation, and as a rule the fracture is reduced with it. You cannot overcorrect it.
5. Draw a line on the X-ray plate, through the tibia in the direction of the weight bearing line, and see where it crosses the astragalus. It should be through its center. If not, get a better reduction.
6. The pillow splint may be used to good advantage.
7. Familiarize yourself with the Böhler method, because it is very valuable, and no doubt will become more popular the more it is used.

GENERAL PHYSICAL EXAMINATION*

E. L. Tuohy, M.D., F.A.C.P.
Duluth, Minnesota

THE morning program readily shows you that I have been given a totally impossible subject, "physical examination." Fortunately, the brilliant and gifted speaker, Professor Luten† from St. Louis, has preceded me and has given to you my introduction. You have seen how carefully he has pointed out the extraordinary value of a proper history, a proper evaluation of the symptoms offered by the patient who comes to consult you, and has discussed the paucity of evidence that is often accumulated after exhaustive routine examination. Those who shall follow me will present to you that objectivity which shall give you peace and calm, whereas I shall give you that subjectivity which may perhaps test your patience.

The public have been greatly charmed for many decades, if not centuries, by objectivity and examination. The quacks have ever been eager to adopt it. So today we see newspaper advertisements of machines in front of which the patient may sit or stand or lie as a vigorous individual may peer through this machine and do the lying afterwards. Many of us have had to deal with individuals of various grades of intelligence, not to say of acquaintance with our language. I might even give this to you in semipoetic form:

Mister da Doc
I been a sic,
Maka da pic,
Pain in the bell,
It hurts like ——.

Finish this up according to your desire—poetry or prose! Translated it means that this individual has been told by some neighbor that if he would come to me, or to a doctor thus chosen, we have an occult machine which may be turned toward him and an X-ray be made of his interior. From that (giving no credit whatever for the use of intellectuality in attempting to extract his story or to properly proportion it), he will be able to find out the cause of the internal discomfort which happens to be in the instance gastro-intestinal.

Out of such basic attitudes comes the notion held by many of our leaders that routine examinations will tell us all needful things. That this is held even in high places is evidenced by the effort on the part of the A. M. A. and this State Association and others to carry on a worthy endeavor intended to popularize periodic health examinations. It is part and parcel of the same notion now carried on by many public laboratories or health extension institutes based upon the belief that by taking a certain series of notations, measurements of one sort or another, one can arrive at an estimate of the status of the individual and judge accurately his life expectancy. I need not bring into the argument at all the obvious fallacy involved in the sending of a specimen of urine to this or that laboratory, and from that magic fluid some static sage may conjure up your future or expeditiously divine the type of pruning needful for your family tree. At least we know the chief thing that happens is the diversion of some $25 from the local community to Chicago or some other city which boasts of such talent.

It is said that the great Voltaire was so very critical of our profession that he thereby evidenced his extreme interest in it. The modern Voltaire is no doubt George Bernard Shaw, who is so critical of us that he exhibits his true appreciation of our possibilities. Critical as was Voltaire of our profession, he was even more critical of the church; he was rather roundly condemned by both. So it is stated that at the time of his death a priest was sent for who came in. Still in his doubting and quizzical attitude, Voltaire said, "Who are you?" The priest replied, "I come from God." Voltaire, half dead, wheezed, "Your credentials, please."

So what are my credentials? Whence have I come? Well, I have practiced medicine rather intensively for twenty-five years, and it just happens that I have been associated most of the time with unusually well poised confreres, trained in various specialties. I know therefore how valuable routine examinations may be. I began as a laboratory man. I had the first modern fluoroscope brought into the northern part of this state. I did the first spinal puncture, so far as I know, that was done in my county and gave the first antimeningococcic* serum intraspinally in Minnesota. My active interest in laboratory routine has been far too intensive to lead me to condemn the practices that my successors, dealing with objectivity, are going to present to you, but I am here to tell you that 75 to 80 per cent of the folks that come to us will have no surcease, no comfort, no benefit whatever from any or all isolated and extensive detail. Such will give great comfort and satisfaction to 10 per cent of complainers. For 15 or 20 per cent, they will help profoundly in ruling out organic diseases, but if they apply spinal punctures and cystoscopies and such forbidding routine upon a mass production industrial basis, they will drive many neurotics to the shelter of the Christian Science fold or to the sublime vacuity of chiropractic.

---

*From the Department of Medicine, The Duluth Clinic, Duluth, Minn. From stenographic report of address before the annual meeting of the Minnesota State Medical Association, Minneapolis, May 5, 1931.

†Professor Luten's address on Cardiology and the General Practitioner appeared in the October number of the Journal.

I therefore enunciate a statement of principle with which I am sure most of you will agree: We must all begin with as distinct an understanding of the complaints the sick individual presents as it is humanly possible to get, and then we may apply such tests and technical adventures as judgment and experience dictate, which may result in a maximum both of information and benefit. First of .all find out why the individual presents himself to you and listen attentively to his story. The real art of medicine is the art of getting a history. Professor Luten has already propounded that thesis logically and convincingly. This is the soundest of medical tenets; ancient and modern. Permit me to read to you briefly from the remarks made by Professor Charles P. Emerson, well known teacher of Indianapolis, in talking on this same subject:

> "In this age of standard output and mass production, you cannot deal with medicine and its problems as one would with fabrics, wood or steel. Patients are not alike. Medical students come to admire the consultant who will see a patient for two minutes, then refer him to the various sets of departments, eye, ear, nose and throat, psychiatric, roentgenological and otherwise, and then take five minutes in which to round up the situation, and treat the patient. This may be good business but it is very bad medicine. I do not even believe it is good business. It does not work."

He says that the more laboratory work he has done on patients the more necessary was it to find out why he had any at all and how to interpret it. I tell you a great deal of the cost of physical examination is not the fault of the medical profession but the fault of folks who fancy that unless you institute a long sequence of objectivity, they aren't getting anything for their money.

That great medical philosopher of Minnesota, William James Mayo, some years ago enunciated the proposition in my presence, "Why should people have to pay you or any doctor who needs a great series of equipment and a lot of detailed examination in order to help him make up his mind? Why isn't it just as valuable that you are able to use your experience, your judgment, your analytical powers and give the man that opinion, without this objectivity?" Like many philosophers who speak so vividly, so honestly and so correctly, of course he went right on to apply that principle in his practice at Rochester and developed a remarkable line indeed, including Dr. Braasch. (I single out the cystoscope not because of any inability to appreciate its virtues but because of an inherent horror of its vices.) There is a very faulty assumption not only by the laity but many physicians that the Mayo Clinic and other good clinics throughout the world magnify and emphasize routine examinations. I wish to assert that no clinic can survive that has not early learned that success is unattainable without the utmost use of the human intellect, and the keenest analysis of that subject most difficult to understand, namely, the human consciousness. It is God's greatest gift to man; and, by all odds, the greatest tyrant inducing disturbances which bring 75 to 80 per cent of our patients to us suffering from this or that. They are usually called neuros. I introduce the painful subject only to dismiss it. It is that type of individual that challenges the medical profession today, from the standpoint of the expense of having an examination, the effort involved in finding out his difficulties, the lack of knowledge of world affairs on our part, the inability to plumb the depths of social relationships, insulating so many of our finely trained fellows from their patients. And what a great disadvantage! Because a man with good personality and intelligence even though a faker or a quack establishes an emotional contact that binds irrespective of logic or reason. Therefore, learn to sit down and listen to your patient's story. Write it out as it is given to you. Keep records.

---

*The late Professor Frank Wesbrook, just back from New York, had been given some of the earliest product by Flexner at the Rockefeller Foundation.

It is not easy to get a history. Many people camouflage their real complaint. They lead you astray. They have seen other doctors and they wish to know what you think about their problems. They give you a story that leads away from the main issue, which is probably fear of cancer or fear of going insane or fear that the mother-in-law may not go home. One needs to be observant and skillful; to check them up, criss-cross back and forth. But write down your gleanings; some of these are very general impressions.

Let me cite an illustration! It has only recently come into our consciousness that there is such a thing as hypoglycemia occurring in normal individuals under emotion or strain. They present a curious syndrome. It may suggest gastric or duodenal ulcer and on occasion is associated with tachycardia. I recall a man who had spent three weeks with a cardiologist trying to get straightened out. His story emphasized a sudden tremulousness and weakness with fast heart beat; he felt very, very uneasy. When he came to the doctor he had only the story of these things. I wrote all that down; but I didn't tumble to what he had. I went ahead and examined and talked to him on the basis of a neuropath with cardiac signs. The next day, in looking over my chart, I said, "Here we are. What was the matter with me? Where was my thinking apparatus?" I called this man back and said, "Did you have a very good night the last two nights?"

He said, "No, I get that same thing. It wakes me out of my sleep."

In general, people do not awaken from neurotic discomforts. I said, "I know what is the matter with you and I totally overlooked it the other day. Take some chocolate or a chocolate bar, put it down by your bed, and just as soon as you feel that coming on, take two or three bites and your distress will go away. Try it." It worked like magic. My explanation satisfied both of us. It is not my purpose to present a monograph upon the subjective manifestations of entities as real as hypoglycemia. Rather do I wish to borrow from the popular province of radio the illustration of "tuning in." I am sure we saw cases of tularemia prior to an epoch making observation of an interne at St. Mary's hospital. He found the first case of tularemia in Duluth by reading the *Journal of the American Medical Association* and possibly MINNESOTA MEDICINE. We now know we are "tuned in" on tularemia. Likewise on Malta fever. Diagnostic leads orient the historical approach. The danger of "seeing" a diseased gallbladder in every well nourished dyspeptic simply illustrates the incalculable need of judgment and honesty. Questions may be less leading than informative: "Did you have a sore on your finger before you had the lumps up here (axillary)? The tularemic man then divulges the rabbit episode. "Did you, sir, before you had this feeling that we are talking about (hypoglycemia), go without food?" "Yes, I went without food. I was on a considerable bat the night before. The next day I thought I wouldn't eat anything and my wife said, 'You had better go out and get some fresh air'." He walked rapidly for four miles, exhausted all the glycogen in his body, had this hypoglycemia, called a physician and was three weeks in the hospital under the combined medical and lay impression of "acute cardiac dilatation." The episode should not appear in medical annals but in certain addenda to the Wickersham report!

I spoke of judgment, and what a thing is judgment! How does one get it? You get judgment by reading, by coming to meetings like this, watching patients who are operated upon, cultivating acquaintance with autopsies and pathologists. One gets it through contact with his fellow-men; it comes in a good many forms. I think you see what is on my mind. I introduce these other men. I ask you to listen attentively to their warnings and exhortations. Specialistic technic is most valuable, but do not reach out for it until you have gone as far as is reasonable with simple processes of analysis and a thoroughgoing exhaustive review of your patient's major complaints. Do not try to buffalo the patient or yourself by directing her attention away from a sore tongue to a malposition of the uterus or laceration of the cervix, because, as a rule, she is right. You should watch these folks with burning, painful throats that you call neuros. You should keep in touch with the best medical meetings of the country. For instance, I asked an observant colleague, "What was the best thing you got out of the meeting of the American College of Physicians at Baltimore in March of this year?" The answer came back, "Minot (without the help of Murphy) gave a talk on the overlapping of pernicious and secondary anemia." Some months previously some of us had hit upon the same notion, that some patients with painful throats and sore tongues even without classical blood (laboratory) changes indicative of primary anemias, are revivified when treated with large doses of iron and raw liver given in cold tomato juice. Thus have I used up all my time in my discursive approach to the patient. This is just as well. You are as familiar as I am with the technic of examinations.

THEELIN AND THEELOL

The announcement three years ago of the separation of a potent ovarian hormone from the follicular fluid by Allen and Doisy marked a distinct step in the direction of progress. The product had an estrus-promoting activity that could readily be assayed. Other investigators also have been engaged in the study of ovarian hormones, and medical journals carry accounts of a considerable number of products, each designated by some trade name. A new era was ushered in when Doisy announced, at the thirteenth International Physiological Congress in 1929, the isolation of a hormone in crystalline form. The Council on Pharmacy and Chemistry of the American Medical Association adopted the name "theelin," selected by Doisy, as the nonproprietary designation to be used in New and Non-official Remedies for the ovarian hormone made by the process of Doisy. Last year Doisy and his co-workers recorded the discovery of a second estrogenic substance in the urine of pregnant women. It is a triatomic alcohol for which the name theelol has been proposed. Theelin appears to be approximately twice as active as theelol in adult spayed rats, whereas, theelol is six or seven times as active as theelin in immature female rats. It is too early to speculate on the possible uses of these two substances. (Jour-A. M. A., July 4, 1931, p. 33.)

HEALTHOLA DIABETIC FLOUR NOT ACCEPTABLE FOR N. N. R.

Healthola Diabetic Flour, according to the label on the package, contains protein, 49.73 per cent; fat, 24.56 per cent; carbohydrates, 15.92 per cent, and contains no sugar or starch. According to the advertising of the distributors, Healthola Diabetic Flour Co., Huntington, W. Va., "Healthola is a flour made from an imported vegetable." No statement of the identity of the product is contained on the package or in the advertising nor is there a statement that in the body the protein contained in the product is largely converted into carbohydrate. The Council on Pharmacy and Chemistry finds Healthola Diabetic Flour unacceptable for New and Non-official Remedies because its identity is not declared on the label and in the advertising; because its name is not descriptive of the composition but therapeutically suggestive instead, and because the claims are misleading and unwarranted. (Jour. A. M. A., July 11, 1931, p. 103.)

FROM N.N.R. TO THE U.S.P.

Of the forty new products in the United States Pharmacopeia X, thirty-one came from New and Non-official Remedies. No better recommendation can be given for "N.N.R." (Jour. A. M. A., September 26, 1931, p. 931.)

INTRAVENOUS UROGRAPHY*

William F. Braasch, M.D.
Rochester, Minnesota

IN the differential diagnosis of abdominal disease a generation ago, surgical lesions of the kidney were often overlooked, but with the development of cystoscopic and allied data they have been recognized more frequently. The necessity of excluding the kidney in cases of doubtful diagnosis, and the fact that it is better for the patient to have a renal lesion discovered by cystoscopic examination than by abdominal exploration was realized slowly. Patients generally were not submitted to urologic examination because of the comparative inaccessibility of such examination and the technical difficulties involved; nevertheless the desirability of a method which would eliminate these factors and which would be available for general use was obvious.

The solution of the problem was made possible by the discovery by Rowntree and his associates that a large amount of sodium iodide given intravenously was excreted by the kidney in sufficient amounts to permit visualization of the urinary tract by the roentgen rays. The application of the method was not widespread, because visualization of the renal pelvis and ureter was uncertain and inadequate, and because of the systemic reaction of many patients to the presence of free iodine in the system. It remained for German chemists to discover that iodine when organically combined was better tolerated and afforded clearer visualization of the urinary tract. Roseno of Cologne was the first to make this discovery, but unfortunately the agent he suggested was toxic. Shortly afterward it was found that another iodine-bearing compound called "selectan" was even more opaque to the roentgen rays and was not toxic. As the result of the combined work of Swick, Binz and von Lichtenberg, this compound was brought out in the form of a substance called "uroselectan." At the same time Bronner of Cologne discovered another form of organically combined iodine which was similarly nontoxic and afforded even sharper visualization when employed intravenously. This substance was called "abrodil." Both uroselectan and abrodil have been placed in the hands of the American profession and have been widely used. The former has been named "iopax" and the latter "skiodan."

Intravenous or excretory urography offers the medical profession an opportunity to obtain data concerning renal conditions in a comparatively simple and practical manner. Although in many cases it will not be sufficient in itself to determine the exact condition of the upper part of the urinary tract, and additional data will be necessary to complete the diagnosis, nevertheless it will often give a better idea of the existence of a renal lesion and its nature than could be obtained by any other method short of cystoscopic examination. It should be employed in every case in which there is any question of the existence of renal disease other than nephritis, and it will undoubtedly lead to the recognition of renal lesions which are now overlooked.

The method will be of great help to the urologist, since it offers the possibility of obtaining additional data which were not available by previous methods. Its greatest value will be in the possibility of investigating the upper part of the urinary tract in cases in which cystoscopic examination is physically impossible or inadvisable. Such cases will include deformities involving the urethra or bladder, contracted and markedly diseased bladders, obstructions to the ureter, conditions otherwise inaccessible, and many cases in which the patients are children.

When intravenous urography is employed in general diagnosis it will be of greatest value in the recognition of urinary stasis, and in the identification and localization of renal and ureteral lithiasis. There should also be less difficulty in recognizing the frequently overlooked disease, hydronephrosis, and in identifying and localizing shadows in the renal and ureteral areas which were suggestive of lithiasis. The determination of the functional capacity of the kidney involved, as well as that of the opposite kidney, should be of exceptional value to the general surgeon.

TECHNICAL CONSIDERATIONS

The technic of administration is comparatively simple. The patient is given the usual preparation for roentgenography, and the iodide compound is injected slowly either by the gravity or syringe method, with the patient in a recumbent position. At present, skiodan is the medium of choice because its administration is not accompanied by untoward symptoms and since it gives clearer visualization than iopax. It is ready for use in sterile ampules in 25 c.c. of a concentrated solution. In recent months iopax has been modified, and claims have been made that it offers unusually good visualization without causing subjective symptoms.

---

*From the Section on Urology, The Mayo Clinic, Rochester, Minn. Read before the Minnesota State Medical Association, Minneapolis, Minnesota, May 4 to 6, 1931.

Attempts have been made to concentrate a maximal amount of the excreted substance in the renal pelvis by both excretory and mechanical methods. The former may be somewhat abetted by limiting the fluid intake for several hours prior to urography. Retention of the medium may be attempted by placing the patient in the Trendelenburg position and by placing a compression bag over the lower part of the ureters for ten minutes before exposure.

Intravenous urography is contra-indicated only in case of advanced renal insufficiency or general weakness. I have employed it, however, for several patients whose blood urea was 100 mg. for each 100 c.c. of blood and for others who were feeble, without observing any ill effect. A serious objection to the method is the exorbitant cost of the iodine compounds which are now available. It is to be hoped the cost will be brought to a level which will permit of their more general use.

In describing the advantages which intravenous urography offers in general diagnosis, it should be noted that there are a number of factors which militate against its universal employment; they are as follows: (1) visualization of the renal pelvis is frequently too dim for exact interpretation; details of calices, particularly the minor calix, are frequently quite obscure; (2) visualization of the ureter is often fragmentary and inadequate; (3) exact urographic interpretation is difficult without considable experience; (4) it is necessary to have cystoscopic data in order to obtain a complete diagnosis in most cases and to exclude vesical conditions, and (5) reflex inhibition of renal excretion interferes with appraisal of renal function.

INCOMPLETE VISUALIZATION

Unfortunately, the intravenous urograms do not afford a uniform degree of visualization. For some unknown reason, apparently an idiosyncrasy, kidneys which are otherwise normal will excrete a variable amount of the iodine compound injected intravenously so that the renal outline is frequently too dim for interpretation. Complete failure of excretion may result because of the reflex action from intrarenal stone, and this may be confused with lack of function. With renal insufficiency, as indicated by blood urea of 100 mg. or more for each 100 c.c. of blood, excretion of iodine will be inadequate to visualize the renal pelvis. Frequently one side will be fairly well seen and the other will be too dim for interpretation. One must not expect to have the pelvic outline as clear as that observed with retrograde urography. It is often necessary to inspect carefully the various films taken at different periods after injection in order to obtain an approximate idea as to the outline of the pelvis. In all such cases retrograde urography and allied cystoscopic observations should be employed.

UROGRAPHIC INTERPRETATION

The difficulty of interpreting the intravenous urogram may offer a serious impediment to its universal employment. Exact interpretation is dependent on wide experience in recognizing the normal and abnormal outline of the renal pelvis. Although in a large number of cases the condition will be easily recognized, there will be many in which interpretation, without the benefit of wide experience, may be difficult. Furthermore, additional data such as can be obtained only by means of the cystoscope may not alone be desirable but necessary, in order to obtain accurate interpretation of the urograms as well as a complete evaluation of the conditions present. The data obtained from the intravenous urogram are often only complementary to the cystoscopic examination, and the ability to recognize its limitations is necessarily dependent on a wide urologic experience.

HYDRONEPHROSIS

In most cases in the diagnosis of hydronephrosis, intravenous urography is preferable to retrograde urography (Figs. 1, 2 and 3). In spite of every precaution that may be taken there is always a possibility of infecting the kidney by means of retrograde catheterization and urography when retained urine is present. Danger of infection is completely obviated by intravenous urography. I have never observed any irritation in the renal pelvis as a result of retained medium injected intravenously, although some patients with hypersensitive bladders will complain of vesical irritation. Another advantage of intravenous urography is the coincident visualization of the opposite side, permitting comparison of the two renal pelves. As a result it has been found that the incidence of bilateral hydronephrosis is undoubtedly greater than had been previously supposed. Pyelectasis in the opposite kidney may not show any symptoms. Intravenous urography is also preferable because it usually enables one to determine more accurately the site of ureteral obstruction. It is obvious that surgical treatment depends largely on whether the obstruction is in the lower or upper part of the ureter. With retrograde urography the injected medium may stop at the level of the kidney and there may be no evidence of it above the point of obstruction. This may occur with a number of lesions such as neoplasm of either cortical or pelvic origin, occluded renal tuberculosis, ureteral angulation and extrarenal pressure. If there is sufficient renal tissue to secrete iodine, intravenous urography offers the only means of determining the nature of the lesion causing such obstruction.

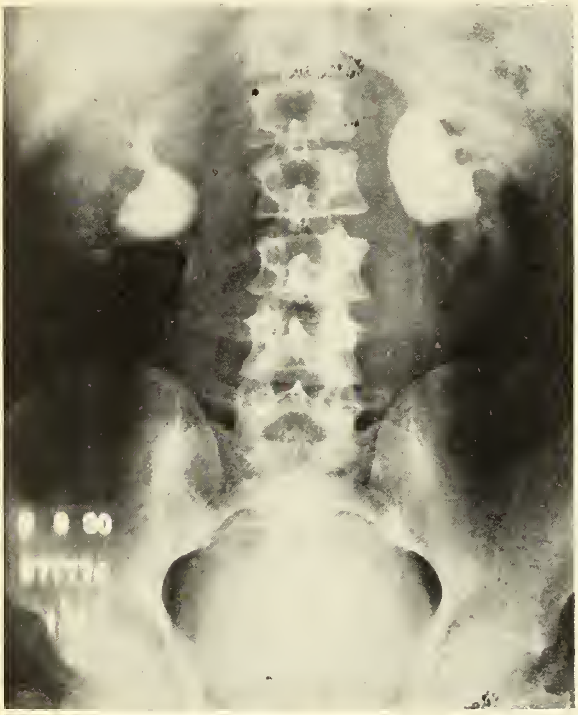

Fig. 1. Intravenous urogram, showing bilateral hydronephrosis, and obstruction at ureteropelvic juncture.

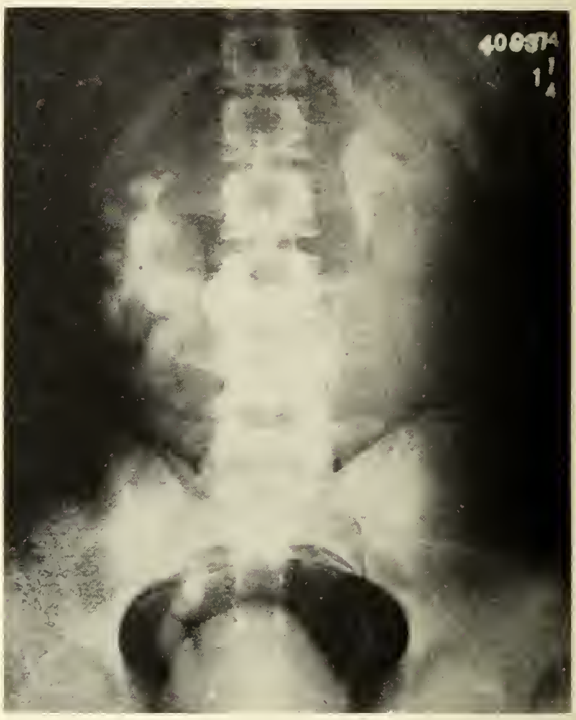

Fig. 2. Intravenous urogram, showing right hydronephrosis and hydro-ureter, with obstruction at the intramural portion of the ureter.

LITHIASIS

It is well known that shadows frequently appear in roentgenograms of the urinary tract which are difficult to identify without cystoscopic data, and as a result the diagnosis may remain doubtful. Surgeons have often explored the kidney or ureter for stone unsuccessfully, with no more exact evidence than was afforded by the roentgenogram. With intravenous urography such shadows can usually be identified and localized by the general profession (Fig. 4). Not alone will the urogram determine whether shadows are in the kidney or ureter, but it will determine their exact location. In the majority of cases the shadow of the stone is visible in the outline of the involved pelvis or ureter more distinctly than in the retrograde urogram. The method will also permit recognition of the comparative renal function of both kidneys and demonstrate any coincident disease or anomaly which may exist in either kidney. If small renal stones are present, the lack of detail in the outline of the calix or pelvis may not permit identification or localization. The method is of value in visualizing the best method of surgical approach to stones situated in the ends of the calices as well as any deformity or dilatation of the calix affected. Localization of a stone in the ureter also may be accomplished more accurately and with much less inconvenience to the patient. It obviates the danger of serious secondary infection which occasionally occurs in the presence of an occluding stone in the ureter. As a rule, evidence of stasis will be present in the ureter, accompanied by a variable degree of ureterectasis. This may be either general or localized to the portion of the ureter adjacent to the stone. If it is not possible to visualize the ureter because of diminished renal function or for technical reasons, it will be necessary to employ retrograde urography.

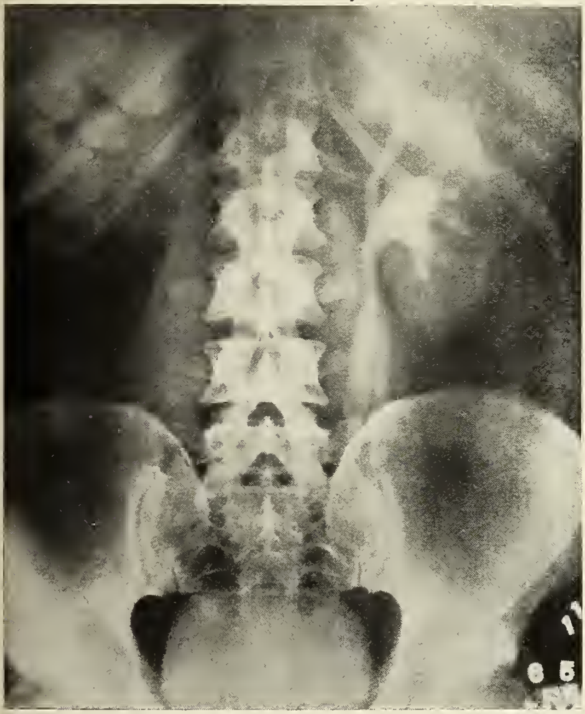

Fig. 3. Intravenous urogram, showing huge hydronephrosis and hydro-ureter on right side with complete duplication of renal pelvis and ureter on the left.

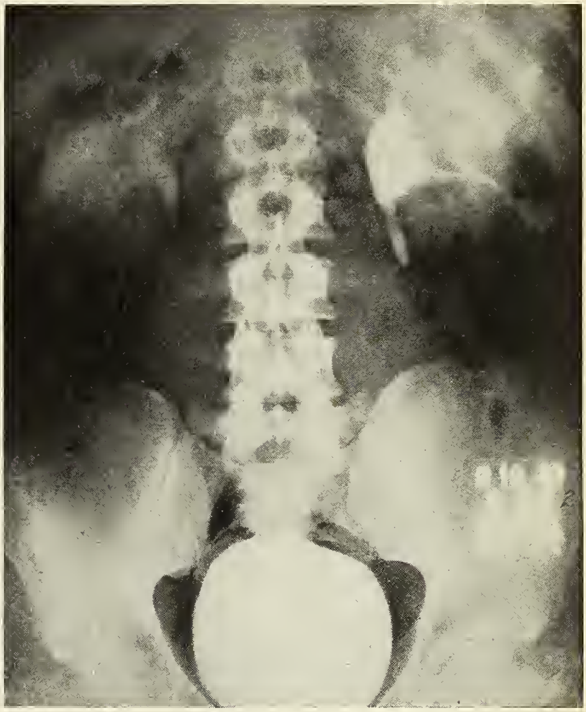

Fig. 4. Intravenous urogram, showing stone in left upper ureter causing obstruction; a shadow is visible in the upper part of the ureter.

RENAL TUBERCULOSIS

The lack of detail observed with intravenous urography frequently renders the method of doubtful value in the diagnosis of renal tuberculosis, renal tumor, and polycystic kidney, particularly in the early stages. The recognition of early renal tuberculosis often depends on the recognition of deformity in the minor calices so that their clear visualization is necessary. In order to accomplish this, retrograde urography is usually preferable. When ureteral catheterization is impossible or contra-indicated, the difference in visualization of the two kidneys may be of value in the recognition of tuberculosis. If, for instance, the bacillus of tuberculosis is found in the urine and a normal kidney is visualized on one side, evidence of delayed or diminished visualization on the other side, even though not clear, would indicate disease. With stasis resulting from stricture the deformity with tuberculosis is occasionally clearly visualized. However, it is usually inadvisable to depend on the intravenous urogram alone in the surgical treatment of renal tuberculosis, since catheterization of one or both ureters is usually necessary to determine if one kidney is normal. When one kidney has been catheterized and found to be normal, and it is impossible to catheterize the other, intravenous urography may be of great value.

RENAL TUMOR

Renal tumor in its early stages, or when situated so as to cause little deformity in the calices or pelvis, may also be difficult to recognize in the intravenous urogram (Fig. 5). The more advanced the lesion and the greater the pelvic deformity the more readily will it be recognized. Failure of visualization of the renal pelvis, or the outline of scattered calices in contrast to a normal pelvis and calices on the other side, may be of value in the identification of abdominal tumor. The detailed outline of the deformed, elongated calices regarded as typical of renal neoplasm will seldom be clearly visualized and the retrograde urogram will often be necessary.

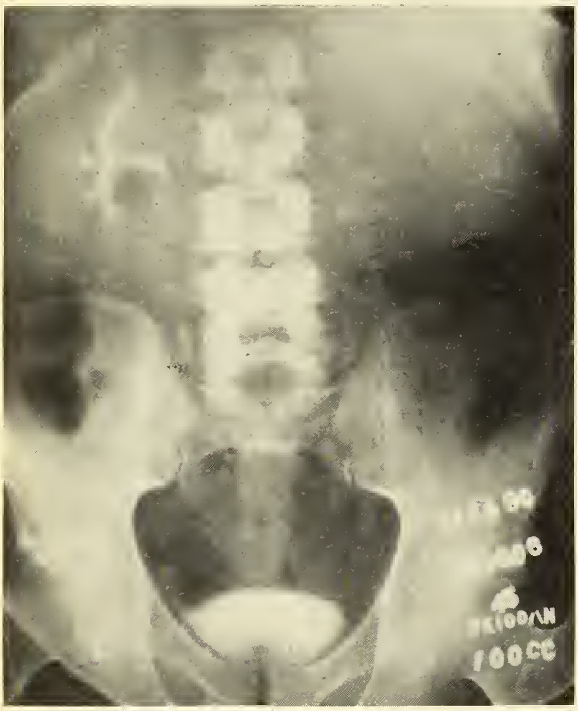

Fig. 5. Intravenous urogram. showing fragmentary calices dimly visible in a case of large left abdominal tumor. A diagnosis was made of left renal tumor; the right kidney was normal.

Polycystic kidney can be easily overlooked in the intravenous urogram. It is well known that excretion of dye is delayed and diminished with polycystic disease. As a result visualization of the renal pelvis and its details may be quite inadequate and may be accomplished only in films made a long time after intravenous injection. In the presence of stasis, however, the films may reveal an outline which is readily recognizable. It should be remembered that secondary stasis occurring with either of these conditions may be confused with the primary etiologic lesion.

RENAL PTOSIS

Intravenous urography should be of general diagnostic value in cases of renal ptosis. The degree of renal excursion can be determined by urograms made in both the dorsal and erect position. Of greater importance is the recognition of stasis in either renal pelvis or ureter, since this is the most significant factor in determining the advisability of nephropexy.

ANOMALY

The possible existence of anomaly of the kidney and ureter is usually overlooked in abdominal diagnosis, as well as in the course of cystoscopic examination, or even retrograde urography. Intravenous urography will undoubtedly determine the existence of anomaly involving the upper part of the urinary tract much more frequently than was possible formerly, and in many cases when clinical data would not indicate it. Duplication of the renal pelvis may easily be overlooked in the retrograde urogram if only one of the pelves is outlined and resembles a normal pelvis. Renal fusion and ectopic kidney are easily overlooked if the pelvis appears to be in a normal position. Intravenous urography visualizes both pelves, and their relation in position and outline and will usually determine the type of anomaly present.

LESIONS IN THE LOWER PART OF THE URINARY TRACT

The relation of the ureter and the kidney to lesions in the bladder and prostatic urethra can best be ascertained by intravenous urography. In fact, in the presence of a large tumor of the bladder involving the ureteral orifice, or of extensive prostatic obstruction, it is frequently impossible to determine the condition of the ureters and kidneys by means of cystoscopic examination and ureteral catheterization. If on cystoscopic examination the tumor in the bladder is found to involve the ureteral orifice, it is usually impossible to catheterize the ureter and it may be difficult to determine its condition and the function of the kidney on that side. With intravenous urography the dilatation in ureter and pelvis, as well as visualization of renal function on the affected side, is made possible. This is of great advantage to the surgeon, particularly with a view to the possibility of transplanting the ureter or the necessity of performing nephrectomy. Incidentally, the cystogram resulting from intravenous urography may also show the deformity of the bladder caused either by a filling defect from a protruding tumor or pathologic change subsequent to prostatic obstruction. In fact, with every case of vesical neoplasm, an intravenous urogram should be made as a routine. Similarly, with prostatic obstruction visualization of ureterectasis or pyelectasis which might exist without any clinical symptoms to suggest it would manifestly be of considerable value. In the course of intravenous urography many unsuspected complications are frequently visualized, such as hydronephrosis, anomaly, or absence of one kidney.

It is evident, therefore, that, with the recent introduction of intravenous urography, medicine and surgery have been given a noteworthy addition to the methods of diagnosis. The medical profession has not yet awakened to the full realization of its adaptability or its general diagnostic value. In the course of time the ability to interpret the intravenous urogram will become more general. At present, however, it is still limited largely to the recognition of stasis and the identification of lithiasis; the necessity of correlation with other urologic data remains.

THE VALUE OF THE ROENTGENOLOGIC EXAMINATION OF THE CHEST*

Walter H. Ude, M.D.
Minneapolis

MEDICAL opinion has passed through many changes during the past year with regard to the place of roentgenology in the diagnosis of diseases of the chest. Viewed comparatively recently with open hostility by our most expert physical diagnosticians, it is now accepted more and more as the most valuable method of study at our disposal. Instead of having his field referred to as "bastard pathology" (Sir Thomas Horder), the roentgenologist is now being accepted as an expert consultant whose opinion must be given all due consideration, even if it brings out factors entirely at variance with physical findings. The clinician of today is the close friend of the roentgenologist, and the feeling existing between them is one of mutual admiration for each other's work. Where they thus work harmoniously, the clinician admitting his lack of expert training in roentgenology, and the roentgenologist qualifying his conclusions by possible errors in technic as well as by his not possessing the very important factors of the history and clinical course, these two will be of the utmost help to each other in the attempt to reach a diagnosis.

In discussing the value of the roentgenologic examination of the chest, one should exclude all studies based on roentgenograms which are lacking in technical quality, or which are interpreted by one with insufficient experience. The rapid development in this field of diagnosis has given us all the factors necessary to produce films of the best quality. Our medical schools, both under-graduate and post-graduate, are furnishing more and more well trained roentgenologists. Thus the adverse factors which tend to discredit the roentgenologic examination may be readily avoided. When they are not avoided they should not be used as an accusation against this entire diagnostic field.

The roentgenologic study of the chest may be considerably influenced by the condition of the patient. Numerous circumstances may make it imperative not to remove the patient from his bed, allowing a bedside film only. With improved equipment and our newer methods of technic, this type of study is very satisfactory. Consolidation, atelectasis, pleural effusion, and other gross pulmonary pathology may be thus studied with a high degree of accuracy without annoyance or danger to the patient. However, for the most accurate study of the chest the patient should be able to coöperate sufficiently well so that stereoscopic films may be made with him in the erect position. For the careful study of minimal changes in the lung parenchyma, stereoscopic films are essential. Occasionally, men with wide diagnostic experience discount the value of the stereoscope. However, they recognize the value of having two films made at different positions of the tube, allowing the demonstration of infiltrations on one film which on the other may be overshadowed by the bony structures of the thorax. I venture to state that in a difficult case no roentgenologist will dispense with the aid of stereoscopic films, and in most instances will welcome the aid of the stereoscope. From the usual postero-anterior films of the chest it may be determined whether films in other directions or whether fluoroscopic examinations should be made to aid in arriving at a satisfactory conclusion. Lateral films of the chest are proving of invaluable help in many pathological conditions, and these films may be made at the bedside almost as readily as in the X-ray department.

Fluoroscopy may be of considerable aid in the diagnosis of diseases of the chest, although such observations are often misleading. It should never be relied on for the demonstration of early tuberculosis or other minimal pathologic changes. It may often aid in differentiating a pathologic process which has been demonstrated on the film. Many clinicians include fluoroscopy of the chest as one of the routine procedures in the course of a physical examination. In one of our well known sanatoriums, all patients are fluoroscoped on their first day in the hospital, and the findings are given to the clinician before he sees the patient.

---

*From the Departments of Roentgenology of the Minneapolis General Hospital and the University of Minnesota. Read before the annual meeting of the Minnesota State Medical Association, Minneapolis, May 5, 1931.

The various pathologic conditions which are commonly found in the chest may be readily grouped according to the degree of accuracy with which they may be demonstrated roentgenologically. This discussion will not include diseases of the heart or pericardium. In the following classification the relative degree of accuracy with which the condition is demonstrated is indicated by its position in the group into which it is placed:

A. Diseases of the chest demonstrated roentgenologically with high degree of accuracy:

Diseases of the Lungs

1. Tuberculosis.
2. Lobar pneumonia.
3. Metastatic malignancy.
4. Massive atelectasis.
5. Pulmonary abscess.
6. Bronchiectasis, if studied with iodized oils.
7. Purulent bronchiolitis.
8. Bronchopneumonia.
9. Non-opaque foreign bodies in the bronchi.

Diseases of the Mediastinum

1. Thymic enlargement.
2. Aneurism of the aorta.
3. Substernal thyroid.
4. Calcification of tuberculous lymph nodes.

Diseases of the Pleura

1. Pneumothorax.
2. Pleural effusions:
   - Free
   - Encapsulated
   - Interlobar
   - Mediastinal
   - Hemorrhagic
3. Hydro-pneumothorax.
4. Diaphragmatic adhesions.
5. Calcified pleura.

B. Diseases of the chest demonstrated roentgenologically with moderate degree of accuracy:

Diseases of the Lungs

1. Chronic lung fibrosis.
2. Pulmonary infarction.
3. Pulmonary congestion.
4. Chronic bronchitis.
5. Bronchiectasis, without the use of iodized oils.
6. Emphysema.
7. Pneumoconiosis.
8. Primary malignancy.

Diseases of the Mediastinum

1. Lymphogranulomata:
   - Hodgkin's disease
   - Leukemia
   - Lymphosarcoma.
2. Non-calcified tuberculous lymph nodes.
3. Metastatic malignancy.
4. Mediastinal abscess.
5. Paravertebral abscess.

Diseases of the Pleura

1. Endothelioma.
2. Metastatic malignancy.
3. Thickened pleura.

C. Diseases of the chest demonstrated roentgenologically with difficulty:

Diseases of the Lungs

1. Mycotic infections.
2. Syphilis.
3. Acute bronchitis.

Diseases of the Mediastinum

1. Chronic mediastinitis.

Diseases of the Pleura

1. Pleurisy, acute, without effusion.

Because of its prevalence, tuberculosis of the lungs has been studied most extensively and thoroughly. Its characteristic appearance in the roentgenogram allows detection of the process in its very early stage, often long before any abnormal physical findings become evident. It is therefore clear that a film of the chest is essential whenever this condition is suspected. An adequate X-ray study of the chest which fails to show tuberculosis will rarely mislead the clinician, and is the best available evidence of the absence of this disease. Often extensive tuberculous infiltrations are demonstrated roentgenologically which were entirely unsuspected from the clinical examination. Cavities are readily demonstrated. Knowledge of the extent of the disease is also of importance in connection with the newer forms of surgical therapy. Finally, progress of the disease may best be observed by periodic X-ray examinations.

Although lobar pneumonia may be readily diagnosed clinically, it is often impossible for the clinician to determine its extent or its location. Here the roentgenograms, representing bedside antero-posterior and lateral films, may be of great help, and rarely fail to demonstrate even the very earliest stages of the disease. In this way we have recently been able to show that lobar pneumonia always begins as a triangular consolidation the base of which is at the periphery, and that so-called hilum or central pneumonia is a misnomer and never occurs. We frequently find the earliest area of consolidation in the retro-cardiac region, so that the antero-posterior film alone may not reveal its presence unless one is exceptionally trained to evaluate slight changes in density within the cardiac shadow itself. In these cases the lateral film is very helpful, and often definitely diagnostic.

The use of iodized oil in the study of the chest has greatly increased our ability to demonstrate the presence of bronchiectasis. Without this aid the roentgenologic diagnosis of this condition is often impossible or may be only suspected. Purulent bronchiolitis is clinically readily confused with bronchiectasis. Roentgenologically it has a fairly characteristic appearance, although it may be confused with disseminated tuberculosis. Re-examination to observe progress will confirm the diagnosis.

Bronchopneumonia is most frequently found in the aged and in the debilitated, and usually has a very characteristic appearance. In the past the early consolidations of lobar (alveolar) pneumonia have frequently been interpreted as bronchopneumonia, necessitating later apologies when the consolidation assumed a lobar distribution. Atypical pneumonias such as accompany influenza may be difficult to classify. I consider these to be of the alveolar type in many instances, but this undoubtedly varies greatly with the type and virulence of the infection.

The above classification emphasizes the interesting fact that acute bronchitis is not readily diagnosed roentgenologically. Most of these cases show no demonstrable changes in the lung. Occasionally a soft diffuse increase in the broncho-vascular tree may be present with this condition. This must not be confused with the prominence of the vascular tree found on films made with a comparatively long time of exposure. Stasis in the pulmonary circulation secondary to cardiac disease may also be very confusing, but can be differentiated by the study of the heart itself.

It is not within the scope of this paper to discuss all of the problems associated with the roentgenologic differentiation of the diseases which have been included in the above classification. Many of these do not show characteristic changes in the roentgenogram, and the findings are frequently merely "suggestive." This may apply to any of the conditions which have been enumerated. Further studies, periodic re-examinations, and prolonged observation may be necessary to reach a satisfactory conclusion. In these cases the friendly coöperation between clinician and roentgenologist is absolutely essential.

SUMMARY

1. Roentgenologic diagnosis in diseases of the chest has reached a high degree of accuracy, especially if it is aided by the friendly coöperation of the clinician.

2. Technical factors and a thorough knowledge of the applicability of the various methods of study are of great importance. Fluoroscopy and bedside films may be adequate to rule out the presence of gross pathology, but should not always be relied upon for absolute diagnosis.

3. There is a considerable variation in the degree of accuracy with which the various diseases of the chest may be diagnosed roentgenologically. This is emphasized by a classification of these diseases.

4. A single roentgenologic examination may often be inconclusive. Periodic re-examinations guided by clinical observation may be necessary to reach a satisfactory conclusion.

802 MEDICAL ARTS BUILDING.

THE VALUE OF ROENTGENOLOGIC EXAMINATION OF THE STOMACH AND GALLBLADDER*

Harry M. Weber, M.D.
Rochester, Minnesota

In the three decades which have elapsed since the discovery of roentgen rays, application of roentgenologic methods to study of pathologic changes of the alimentary tract in the living subject has resulted in development of a diagnostic procedure which possesses unprecedented precision and reliability. The roentgenologic method has a fundamental and rational appeal. The information it supplies is largely visual, and hence objective. Herein lies its basic value, and the foundation for the great interest, even enthusiasm, with which roentgenologic procedures are generally received.

Observations made at laparotomy or necropsy may be at variance with roentgenologic data. However, the roentgenologist does not think that this constitutes evidence that the method is limited in its value. He considers, rather, that the observer has not fully appreciated the evidence which the method is capable of yielding. Correlation of data obtained by necropsy and laparotomy, with skillfully elicited roentgenologic findings, discloses not only that this attitude of confidence on the part of the roentgenologist is not unwarranted, but also serves to explain, at least in part, the accruing reliance which others place on the method.

A tendency may have been fostered in some quarters, however, to permit roentgenologic investigation to supplant the carefully elaborated clinical survey of the patient. Obviously such a tendency is to be discouraged. Those who appreciate the efficiency of the roentgenologic method, as well as its limitations, do not fail to evaluate its usefulness in terms of the patient. Little doubt can be entertained that the application of the roentgen rays to the study of disease of the upper part of the alimentary tract has contributed greatly to precision in gastro-enterologic diagnosis, but it is questionable whether or not the physician's burden has been substantially lightened by it. To him falls the lion's share of the responsibility of passing judgment on the results of examination and of determining the procedure which is indicated in investigating the individual case.

Inquiry into the actual value of the roentgenologic method in the diagnosis of disease of the stomach and gallbladder is attended with not a little difficulty. Of necessity, one must consider how valuable it can be made rather than how valuable it actually is in a given set of circumstances. Obviously its utility and significance will be increased proportionately with the roentgenologic experience and skill of the observer, and with the regard for meticulous detail with which the data are elicited and interpreted. The method is all too frequently branded as inefficient only because the physician failed to avail himself of the full benefits which could have been reaped by proper utilization of the procedure. Neglect of such details as careful roentgenoscopic and roentgenographic technic, adequate preparation of the patient, and proper administration of contrast material, accounts for much of the unsound roentgenologic opinion which is promulgated.

Moynihan is quoted by Barclay as having made the statement that roentgenologic examination of the stomach is of more value than all other methods put together. At the present time, the method is so universally utilized that one might prefer to devote time to consideration of its limitations, but I shall endeavor to review, in a general way, some of the specific data which I feel the roentgenologic method can be made capable of providing.

Roentgenologic examination of the stomach and duodenum does not, in any sense, consist in exhibition of a technically good roentgenogram of these organs filled with opaque material. By chance, such a roentgenogram can be diagnostic if the pathologic process is extensive, or if a relatively limited involvement happens to have been projected in precisely the most advantageous manner. An apparently normal roentgenogram is, however, never adequate to exclude the presence of disease. In recommending fluoroscopic examination of the stomach as the indispensable roentgenologic procedure, I am far from desiring to pass as inadequate or impractical the plan of "serial roentgenography" of Cole, and those of his followers who adhere closely to his teachings. I also recognize the excellence and diagnostic precision which the methods of Forssell, Rendich, and Berg are capable of yielding. The fluoroscopic examination, however, carefully and properly performed, can be made to produce a diagnostic efficiency pratically equal to all of these methods, and has the additional advantages of convenience, rapidity, and relative inexpensiveness. The trained gastro-enterologic roentgenoscopist is confident that fluoroscopic investigation permits him to make adequate observations of the external contours of the stomach and duodenum; it allows him to rotate his patient in whatever position is necessary to demonstrate these contours, and by manipulation and compression of the gastric and duodenal walls he secures the essential details of the inner contours of these organs which he admits the methods of Berg and Forssell might demonstrate more clearly and graphically. Obviously the ideal roentgenologic investigation will include any or all procedures which will serve best to facilitate a clear-cut and complete diagnosis. Those who favor the roentgenoscopic method do not fail to appreciate the complementary and corroborative advantages of roentgenography, and do not hesitate to utilize it whenever expedient.

---

*From the Section on Roentgenology, The Mayo Clinic, Rochester, Minn. Read before the Minnesota State Medical Association, Minneapolis, May 5, 1931.

W. J. Mayo once made the statement that only about one patient in ten with gastric symptoms has a gastric lesion. If this is true, the first and most obvious value of roentgenologic examination will consist in the proficiency which it allows of selecting the one patient with stomach trouble on a basis of organic disease, from the overwhelmingly larger group whose complaints are of a functional nature, or whose symptoms are referred to the upper part of the alimentary tract from an organic lesion situated elsewhere in the abdomen. The question uppermost, then, in the physician's mind, when he has decided to submit his patient for roentgenologic examination, is, "Is or is not a gastric or duodenal lesion present?" The roentgenologic method can be made to furnish an explicit affirmation or negation in reply. Study of large numbers of patients who had been subjected to roentgenologic examination of the stomach and duodenum previous to exploration reveals that the roentgenologic efficiency in correctly determining the presence or absence of organic gastric or duodenal disease runs consistently higher than 90 per cent. In other words, not more than 5 to 10 per cent of organic lesions of the stomach and duodenum escape detection by a properly executed roentgenologic examination, and in the absence of roentgenologic signs of disease a gross anatomic lesion can be definitely excluded from the clinical picture.

The roentgenologic method can and does extend its value beyond this point. For the institution of an intelligent therapeutic program a knowledge of the nature of the disease is essential. Is the lesion malignant or benign?

CARCINOMA OF THE STOMACH

The incidence of malignant disease in the duodenum is known to be low, but approximately a third of all carcinomas occur in the stomach, a figure which emphasizes the value of a procedure which will enable the diagnosis to be made as early as possible. In this respect, roentgenologic examination takes precedence over all other methods of investigation. Not only are roentgenologic signs of malignant disease clear-cut and pathognomonic in all those cases in which these conditions are detectable by other methods, but it is capable of revealing lesions which are as yet impalpable, and in which chemical and microscopic examinations of gastric content are not determinative. It is not an altogether uncommon occurrence for roentgen rays to uncover the presence of a gastric carcinoma which gave no other sign of its presence. On the other hand, negative roentgenologic exploration of the stomach for carcinoma almost precludes its presence, since, according to Carman, 95 per cent of carcinomas of the stomach at The Mayo Clinic were roentgenologically demonstrable. In the presence of a palpable tumor of questionable origin, roentgenologic examination distinguishes between intrinsic and extrinsic gastric tumors with greatest accuracy. Further, it has a most decided advantage over all other means of investigation in the clarity and precision with which it establishes the site, extent, and general anatomic characteristics of the process. Such information is of particular value in answer to the surgeon's question concerning operability, and the particular surgical procedure he might see fit to initiate.

BENIGN LESIONS OF THE STOMACH

Although benign neoplasms of the stomach are rarely encountered, the roentgenologist is prepared to recognize them as such when they are present. He is disposed to designate such a lesion as a "polypoid tumor" because he is aware that a considerable variety of histologic types of lesions produce identical roentgenologic appearance. It is also known that especially one histologic type of polypoid tumor, the adenoma, although grossly benign in character, may exhibit microscopic evidence of malignancy. Many of these lesions are entirely unsuspected clinically, but some of them have been shown to be responsible for repeated obscure hemorrhages to which varying grades of secondary anemia are traceable. Adenoma may be single or multiple; the other histologic varieties are usually solitary lesions. Very small polypi are exceedingly difficult to recognize, but those which have attained the size of 2 cm. or more will scarcely ever escape roentgenologic detection.

By far the most commonly encountered benign gastric lesion is the gastric ulcer. Consummate roentgenologic skill is at times required to demonstrate very minute ulcers and those situated high in the cardiac portion of the stomach, yet the diagnosis of gastric ulcer is practically identical in accuracy with the diagnosis of other gastric lesions. Nowadays the roentgenologic diagnosis of ulcer of the stomach is based almost exclusively on the direct evidence of the lesion. The demonstration of the pathognomonic sign of the crater of the ulcer, or the niche, must be elicited, and in the absence of this evidence the roentgenologist hesitates to offer the diagnosis even in the presence of very suggestive indirect signs, such as the incisura, the hourglass deformity, and the diffuse gastric spasm.

Carcinomas of the stomach may become ulcerated, but in dealing with such a lesion it is unusual for the roentgenologic signs of malignancy to be so indefinite or obscure that its carcinomatous nature is not discerned. In other words, there is a definite roentgenologic syndrome with which carcinoma is identified, and a distinctive set of signs which denotes benign ulcer. It must be remembered, however, that certain ulcers of the stomach, which on roentgenologic examination and gross inspection had all the features which we have learned to associate with a nonmalignant process, have been shown on microscopic examination to have malignant cells in their edges, and the subsequent condition of the patient bore out the validity of the microscopic disclosures. In those cases, the roentgenologist can hardly be expected to do more than allow his case to rest when he has offered his evidence of the presence of the lesion. Carman taught that gastric ulcers 3 cm. or more in diameter are likely to be carcinomatous, but ulcers much smaller than this have shown microscopic evidence of malignancy.

The gastric ulcer which occurs in the pyloric third of the stomach merits special consideration. In this situation, any ulcerative process, whether malignant or benign, may produce an obstructing deformity by a combination of spastic and organic changes, which makes roentgenologic determination of the precise nature of the lesion extremely difficult at times. Administration of an antispasmodic sometimes reduces the spastic component to a minimum, and thus lends valuable aid in bringing out the direct anatomic evidence more clearly. Frequently, however, the roentgenologic evidence admits of no more refinement than the report of an obstructing lesion at the gastric outlet. Exploration reveals that this roentgenologic picture may be the result of genuine malignant infiltration, single or multiple benign gastric ulcer, or obstructing duodenal ulcer with associated pyloric spasm.

DUODENAL ULCER

Examination of the duodenum is always included in the complete roentgenologic investigation of the stomach. Tumors of the duodenum are exceedingly rare, but the duodenal ulcer is an anatomic and pathologic entity of great practical importance. Fortunately the roentgenologic method is particularly efficient in demonstrating this lesion. The signs are so constant and reliable that it can safely be said that not more than 5 per cent of duodenal ulcers will escape expert roentgenologic investigation, and, on the other hand, negative results of roentgenologic investigation of the duodenum almost preclude the presence of duodenal disease. It seems necessary, however, to point out that although the characteristic bulbar deformity or the pathognomonic duodenal niche may be obvious even to the inexperienced observer of roentgenologic shadows, the realization of full roentgenologic efficiency is likely to come only to the examiner who is particularly alert, attentive, and expert.

RARER GASTRIC LESIONS

Less frequently encountered diseases of the stomach are syphilis, tuberculosis, and actinomycosis. Gastric syphilis, however, occurs often enough to merit habitual consideration in gastric diagnosis. The roentgenologic syndrome is sufficiently distinctive to make rendition of the diagnosis possible in a high percentage of cases, but even if the roentgenologic evidence is not clear-cut and pathognomonic in every case, yet the presence of a gastric pathologic condition always will be indicated, and the roentgenologic examination may be said to serve a valuable directive and corroborative purpose. Tuberculosis and actinomycosis of the stomach are so rare that they have little practical diagnostic importance.

THE STOMACH AFTER OPERATION

Roentgenologic examination is often utilized to determine the functional behavior of the stomach after one of the various operations used in treatment of gastric lesions, and to aid in finding the cause of occasional unsatisfactory results. The commonest type of lesion one expects to find is the gastrojejunal ulcer after gastro-enterostomy, and local recurrence after resection for malignant growths. The roentgenologic diagnostic problem is made complex because of the physical and functional changes produced by the surgical intervention, and the method is not expected to maintain the precision it has in detection of the primary lesion. As roentgenologic experience accumulates, however, constant improvement in accuracy is noted, and with close coöperation of clinician and roentgenologist, the correct diagnosis is reached in all but a small percentage of cases.

THE GALLBLADDER

Abel and Rowntree, in 1909, showed that phenoltetrachlorphthalein is eliminated from the body chiefly in the bile. Fifteen years later, Graham and Cole applied this knowledge to introduce one of the most remarkable advances in diagnostic medicine, namely, cholecystography. By substituting, in the phenoltetrachlorphthalein molecule, the elements bromine or iodine for the far less radiable chlorine, they came into possession of a dye which makes the ability of the gallbladder to receive and concentrate the dye-laden bile subject to roentgenologic scrutiny. Essentially, then, cholecystography is a qualitative test of the functional capacity of the biliary tract. It is not primarily a method of directly demonstrating pathologic change.

Gallstones, when they contain sufficient calcium, can give primary evidence of their presence on the roentgenogram. The gallbladder, too, when its walls are very markedly thickened or calcified, or when it is enormously distended with bile or fluid, can cast a primary shadow. Most gallstones, however, do not contain sufficient calcium to cast shadows and the percentage of definitely diseased gallbladders which can be demonstrated roentgenologically, without the use of the contrast dye, is so low that prior to cholecystography the roentgenologic diagnosis of cholecystic disease was generally held in rather low regard.

The Graham-Cole method was received with general enthusiasm, and it was soon learned that the extraordinary value of the procedure consisted in the exhibition of failure in function of the gallbladder. After the method had been in use for a time, it was determined that the gallbladder which was found to be pathologic, by the surgeon's gross examination, and by the pathologist's microscopic investigation, was unable to receive and to concentrate a sufficient quantity of the dye-laden bile to make itself roentgenologically apparent. At the present time, Kirklin, whose statistical studies are similar to those of other observers, finds that demonstration of the so-called nonfunctioning gallbladder means cholecystic disease in more than 96 per cent of the cases which he has been able to follow to exploration. It is important to note, in this connection, that in making this study, gallbladders in which there was minimal microscopic evidence of disease were not included as pathologic.

A normal cholecystogram, however, does not imply a normal gallbladder. This fact becomes obvious when one considers the great number of normally functioning gallbladders within the shadows of which gallstones are visualized. Moreover, Kirklin, Caylor, and Bollman demonstrated that a definitely diseased gallbladder does not invariably lose its capacity of concentrating the dye, and that there is no constant relationship between the degree of concentration of bile and that of the cholecystographic medium. Kirklin has repeatedly pointed out that the greatest number of diagnostic errors occurs in the group of cases in which a normal cholecystographic response was elicited, but in which cholecystic disease was found at operation.

Perhaps the most valuable aspect of the normal cholecystographic response is the facility with which it reveals the presence of gallstones. Depending on their calcium content, stones produce areas either of increased or diminished density in the shadow of the gallbladder, and are usually quite obvious. Occasionally, however, the evidence of cholelithiasis is so slight that it can be discerned only by most careful scrutiny.

It has become obvious to me that cholecystography, perhaps more than any other roentgenologic procedure, is out of place in the hands of those who are either unwilling or unable to devote most scrupulous attention to technical detail. This care begins with the administration of the cholecystographic medium, continues with the direction of the patient throughout the time required for carrying out the test, implies individualization of each patient, and ends only when the observer has satisfied himself that the test has been extended to its full capacity.

When consideration is taken of the rather wide gaps in basic knowledge concerning the functional and anatomic changes of the gallbladder in disease, it is a matter of wonder not so much that the procedure is sometimes in error, as that it is so rarely wrong. In evaluating cholecystography, the high efficiency of the clinical diagnosis of cholecystic disease must be kept in mind. In the frank case, cholecystography is corroborative; in the more obscure case it is directive, occasionally perhaps determinative. At all events, it is a laboratory procedure, and as such should not be relied on without other data to affirm or deny the presence of cholecystic disease. Rather let the family physician or the clinician collaborate with the roentgenologist, collect all available information, and estimate the probabilities of disease and its gravity.

THE INDICATIONS FOR AN EXAMINATION OF THE COLON*

Edwin L. Gardner, M.D.
Minneapolis

The mechanism producing gastrointestinal symptomatology usually cannot be attributed to one offending organ alone. An abnormal function of the stomach, or of the liver, or any other part of the gastrointestinal tract is likely to affect the activities of the entire digestive system. This is noticeably true in disturbances of the colon. In order to simplify and coördinate our knowledge, we should be reminded of several fundamental physiological principles of colonic function.

1. The colon is embryologically, anatomically, and functionally two distinct organs. The proximal colon is a thin walled, easily dilatable organ for the absorption of fluids and their dissolved contents, as well as an organ of propulsion of liquid or semi-fluid material; while the distal colon is essentially an organ of elimination, as shown by its stronger musculature, greater tonicity, and greater capacity for vigorous mass peristalsis.

2. The colon is a non-striated muscular tube, whose activities obey the laws affecting involuntary muscle, but with certain adaptation for function. Non-striated muscle responds to tension by contraction, but in the case of the colon, adaptation has normally produced a marked refractory stage after massive peristalsis, lasting 6 to 24 hours, during which stage of fatigue the musculature is comparatively insensible to stimuli for massive contraction. It follows, then, that the normal colon does not show vigorous peristaltic waves, except when influenced by vigorous stimuli such as extend down the digestive tube after the taking of food, or especially upon arising in the morning after a good night's rest. It is this massive peristalsis which forces the stool into the lower sigmoid and rectum. The rectal tension in turn stimulates the defecation reflex. Normally, the rectum is empty, or nearly so, during the greater portion of the twenty-four hours.

3. The motor function of the colon depends upon the balance between peristalsis, on the one hand, and the resistance of muscular tonus on the other. The colon always contracts upon its content, whether it be air or fecal matter. According to the law of "postural tonus," it may contract still further, whether in a resting, contracted or dilated state. In a habitually contracted colon, such as occurs in chronic diarrhea or after the habitual use of cathartics, the stimulus produced by very slight distension may initiate active contractions, while in conditions associated with colonic dilatation only a large bowel content will stimulate motor activity. Whether the bowel is contracted or dilated, it responds to tension by contraction.

4. The digestive tube, like the heart, is autonomous; and the nervous system is essentially a regulator of muscular and secretory function. Through the influence of the nervous system, the digestive tube's irritability and threshold for receiving stimuli are greatly influenced.

5. Distress or pain from the colon is an expression of motor function, *i.e.,* tonus and peristalsis. Pressure of the palpating hand over the colon causes increased tension with resulting discomfort in sensitive cases. Stimuli may be referred to other portions of the digestive tube, either through direct extension from muscle fibre to muscle fibre, or indirectly, through the nervous system. Those symptoms arising from peritoneal irritation or from tugging on the mesentery result from an entirely different mechanism.

6. In spite of much propaganda to the contrary, the colon does not normally completely empty itself every twenty-four hours. A barium meal in the average normal is eliminated in forty-eight to seventy-two hours, and there is abundant evidence to show that the bowel, like the stomach, has a selective action on the foods which it eliminates. It has been shown that certain food residues, or small glass beads fed to healthy medical students, may not be expelled from the rectum until a period of 7-10 days has elapsed. All evidence would indicate that the average normal individual on an average diet will

---

*Read before the annual meeting of the Minnesota State Medical Association, Minneapolis, May 5, 1931.

have one formed stool per day, or possibly two, and that more frequent, mushy stools are the exception, rather than the rule. Normally, there is a great variation, depending upon diet and habit, and perfectly healthy individuals may, without harm, go several days with no stool. The rule often prescribed in "health literature" and broadcast to the public, that "three stools per day, one after each meal, is advisable for health" is ridiculous and likely to make semi-invalids.

What symptoms should direct our attention toward the colon? The patient may have some definite complaint beginning at some definite time, with remissions, or a definite progressive course, in which case the symptoms usually indicate some organic disease. But more often the abdominal symptoms are more or less bizarre and confusing upon first impression, and lead the examiner astray.

A careful history often gives a clue to the cause of the disturbance. The primary symptom or syndrome should always be carefully sought. In many functional colonic disturbances there is a history, dating from childhood or puberty, of either irregularities of evacuation, or, what is especially important, upper or general abdominal symptoms which are relieved or modified by evacuation of the bowels. A family history of chronic dyspepsia of a similar nature, or of migraine, is reassuring of a probable constitutional tendency to colonic disturbance.

As the years go by, the digestive tube may become more irritable and in sequence other symptoms develop, until at the time the patient appears for examination the secondary "spill-over" symptoms may off-hand resemble gallbladder, gastric, or other digestive disease. A careful analysis will again show the relation of symptoms to bowel function, and in the functional cases to fatigue and emotional states.

Pain is the most frequent symptom which causes the patient to consult the physician. The pain, caused by motor disturbances of the colon as a whole, varies from a sense of pressure to severe colic, and is frequently diffusely referred to the abdominal wall just below the navel. The pain may be related to evacuation of the bowels, and is often relieved by the passage of a good stool. It more likely occurs at those times when the colon is most active, namely, after the taking of foods, early in the morning before or upon arising, and after excitement. Localized areas of increased intracolonic tension or peristalsis may cause pain over other areas of the abdomen. A vigorously contracting cecum and ascending colon may be painful enough to cause syncope, and is likely to be associated with nausea and vomiting. In congenital hyperdescent of the colon, where the cecum lies low and is fixed in the pelvis, or when the cecum is bound down by bands or adhesions, paroxysms of pain may be unusually severe. These attacks may be confused with many abdominal lesions, but may be diagnosed by the fact that unless obstruction is present they the quickly relieved by bowel evacuation (as by a warm enema), and very often by belladonna. The giving of a large test enema may reproduce the patient's symptoms by increasing intracolonic tension.

Pain or distress arising from the sigmoidal region is likely to be referred to the rectum and lower sacral region. Pain arising about the flexures may be referred to the upper abdomen or thorax because of the close relation of the colon at these points to the innervation of the lower thoracic segments. Here again should be studied the relation of pain to colon function and its relief by the release of intracolonic tension. Only in an almost complete obstruction does the enema become ineffectual. Pain of various types may reflexly be produced in other organs, but the fact that it comes later in the history than the primary colonic complaint, or is related to colonic function, is sufficient evidence to make its source obvious.

The examination of the stools often furnishes important evidence of a colonic disturbance. Stools which are regularly normally formed, of good size, free from excess of mucus and free of blood (chemical and gross), are very good evidence that no troublesome colonic dyscrasia, either organic or functional, is likely to be present. No one single examination is as important as repeated observation of the stools to exclude colonic diseases. In the absence of bleeding hemorrhoids and fissures, or lesions of the stomach (and swallowed blood must be excluded), the constant presence of occult blood means either an ulcerated mucosa or some bleeding neoplasm. Carcinoma of the cecum may not be evident upon physical or X-ray examination and still cause extreme grades of secondary anemia. Diverticulosis is not associated with the constant presence of occult blood in the stools.

A history of progressive constipation with small pencil or ribbon-like stools indicates the necessity of a careful examination; and a chronic or recurrent diarrhea always requires further study.

An abdominal examination may disclose signs which require further elucidation. Visible peristalsis in the terminal ileum and an occasional slow contraction in the proximal colon is always suggestive of obstruction lower down. Excessive rumbling is common in fermentative dyspepsia, or in narrowing of the lumen. Abdominal distention may be due to a megacolon, gas from obstruction or fermentation, and to fluid from peritoneal exudate. A large cystic mass in the lower right abdomen which contracts under the palpating hand may occur in organic obstruction further down, and very often may be due only to a functionally spastic colon. Inflammatory masses are found in the region of the cecum and about the sigmoid, those in the latter location being most commonly due to inflamed diverticula; and these are usually hard and tender. Neoplasms may be felt anywhere along the course of the colon, but in the cecum and ascending colon may be advanced when the patient comes for examination, because of the easy distensibility of the bowel in this location, and because of the tendency to early ulceration, thereby preventing an early obstruction. In the distal colon obstruction is more likely to develop early in the disease.

Tenderness in colonic disease may be present along the course of the colon anywhere in the abdomen, which is in contrast to the symptom "pain." Frequently, it is present in the region of the cecum, but even more commonly over the descending colon in the lower left abdomen. Secondary symptoms elsewhere in the abdomen may be stimulated by pressure over a portion of the tender colon.

The term "autointoxication" is often applied to a group of general symptoms attributed to constipation and supposed to be due to absorption of some chemical poison. If this symptom-complex is always due to poisons, how can we explain their almost immediate disappearance after stool evacuation? Mechanical distension, with air or dilatable rubber bags, of the rectum or lower sigmoid may in many cases produce the signs of "autointoxication" which immediately disappear as the pressure is released. Observation, therefore, shows that tension in the bowel may produce these symptoms, and none of these hypothetical poisons have actually been demonstrated, although suspected in the occasional case. "Autointoxication" calls for a careful study of colonic motor function. Contents of the proximal colon if in a too liquid state, and if delivered to the colon by the small intestine before proper digestion has taken place, are more susceptible to bacterial action, which may result in the formation of chemical substances more readily absorbable in the excessive fluid medium. Many patients with the chronic irritable bowel, with or without spastic constipation, show excessive small intestinal hypermotility and comprise a group of cases with the autointoxication symptom-complex. No doubt, many of the symptoms in these irritable cases are a reflex expression of abnormal motor function, or increased suceptibility of an irritable nervous system to normal intestinal stimuli.

A detailed sequential history, a careful physical examination, and inspection of the stools (with a chemical test for blood), is usually enough to make a probable diagnosis, and most commonly is sufficient to exclude serious disease, but many cases require a proctoscopic and X-ray examination. An important practical suggestion is that both the proctoscopic examination and the X-ray clyster should be made without a previous cathartic or enema because of the extreme irritability and mucosal congestion which both produce for nearly twenty-four hours. This first procedure may be checked after thorough elimination, but is rarely necessary, and often the picture is confused by the preparation. In every patient a careful general examination should be made, and, when indicated, the entire gastrointestinal tract should be investigated.

SUMMARY

1. Abdominal symptoms, exaggerated or relieved by bowel evacuation, especially if increased by stimulating foods, chilling of the body or emotional strain, require a careful examination of the colon.

2. Colonic symptoms due to organic disease usually have a definite onset, accurate localization, and a progressive course. The symptoms of functional disturbances may have a life-time history; the symptoms are variable and often bizarre, usually not progressive, but exaggerated by dietary indiscretions and nervous and emotional influences. If the symptoms are due to

some general disease, their course bears a close relation to the course of the basic disease (tuberculosis, cardiorenal, anemia, etc.).

3. Unexplained blood in the stools always requires a careful examination, and unexplained anemia may be due to symptomless carcinoma, especially of the cecum.

4. A progressive constipation or diarrhea always requires a careful study of the colon and the stools.

5. Any abdominal complaint with an obscure or atypical history or unusual symptoms demands a careful colonic examination as a part of a general thorough abdominal investigation.

USE OF CINCHOPHEN AND NEOCINCHOPHEN

In consideration of reports of untoward effects, it would be well to discontinue the use of cinchophen and to substitute neocinchophen for it. Even though neocinchophen owes its activity to cinchophen, it is so slightly soluble as to be almost tasteless, devoid of irritant action on the stomach, and of remarkably low toxicity. If cinchophen is prescribed it should be under its pharmacopeial name and not as "Atophan," which is more expensive and is marketed with unwarranted claims. If neocinchophen is wanted it should be prescribed under this name and not under the uninforming designation "Tolysin." In view of the serious though rare poisoning from ordinary doses of cinchophen, the use of this drug should be restricted as much as possible to cases in which other non-narcotic analgetics, such as salicylates, acetylsalicylic acid or amidopyrine, have been tried and failed to give adequate relief, and in which the suffering is sufficiently great to justify the risk. (Jour. A. M. A., August 8, 1931, p. 409.)

THE KAADT DIABETES TREATMENT

Reports are being received that a diabetic treatment is being sent out by the Diabetic Laboratories of Fort Wayne, Indiana, the material as sent to the patient by this concern being signed by C. F. Kaadt, M.D. A quart bottle of the medicine is sold for five dollars, and the patient is asked to disregard the testing of urine for sugar. A request sent to Dr. Kaadt by the American Medical Association Bureau of Investigation, requesting that he declare the composition, did not bring this information. Instead, it appeared by the reply that while Dr. Kaadt is willing to let laymen infer that he has a cure for diabetes and sells this remedy on the mail-order plan, telling diabetics that when using it, it is unnecessary for them to use insulin or diet, he is, as yet, unwilling to give the medical profession any information on the subject. This, in spite of the fact that he admits that he has used his remedy for nine years and that he has never failed to produce a cure. (Jour. A. M. A., August 15, 1931, p. 479.)

INDICATIONS FOR SPINAL PUNCTURE*

Henry W. Woltman, M.D.
Rochester, Minnesota

THE most common purpose of spinal puncture is to obtain cerebrospinal fluid for examination. It is not indicated until the physician has some idea of what he is looking for, whether change in color, cytologic change, change in chemical composition, organisms, or hydrostatic changes. The inference is clear; examination of the fluid should be complete and a neurologic examination should precede the puncture. One should know beforehand whether or not the optic disks are choked, since presence of this phenomenon constitutes a warning that a situation exists in which puncture is not always safe.

At the head of the list of indications for spinal puncture I should place suspicion of poliomyelitis or of epidemic meningitis. In children, the ordeal will be made less trying by preliminary administration of a small dose of a sedative such as sodium *iso*-amylethyl barbiturate (sodium amytal). The seasonal incidence and the presence of epidemics aid in making a decision, and the urgency of early treatment justifies the procedure.

Symptoms suggestive of meningeal irritation, such as headache, backache, reflex spasm of the nuchal muscles on flexion of the head on the thorax, and a positive Kernig's test, whether or not accompanied by fever, in the absence of choked disks, and often an adequate period of observation, usually justify spinal puncture.

A cloudy fluid generally indicates that some organism is at work; cultures and smears should be prepared and carefully studied. Tuberculous meningitis is usually suggested by the clinical course, pleocytosis and low values for chlorides in the fluid. The diagnosis is verified by demonstration of *Mycobacterium tuberculosis* in the fluid. Actinomycotic meningitis, which is seen from time to time in rural communities, frequently displays surprisingly few signs of meningeal irritation, although the pus mixed with the spinal fluid may be so thick that suction is required to obtain it.

Suppurative otitis media is always followed apprehensively, and when signs of intracranial extension occur, puncture is usually indicated. Pus in the spinal fluid, without organisms, is not infrequently encountered; this situation is not always so grave as might be anticipated. When Queckenstedt's sign, making pressure on each side separately, is employed to assist in the diagnosis of sinus thrombosis, one must bear in mind that a response on unilateral pressure, particularly on the left side, is often absent normally, as first pointed out by Ayre.

Puncture is to be avoided, as far as possible, when one is dealing with an abscess of the brain; there is always danger of extension or rupture of the abscess. It is sometimes impossible to tell, however, whether an abscess is sufficiently mature to be operated on. Puncture may then be performed, removing as little fluid as possible. If polymorphonuclear leukocytes predominate, operation usually proves fatal, but if lymphocytes predominate, the outlook is relatively good.

Spinal puncture is usually indicated when there is evidence of progressive impairment in function of intracranial and intraspinal structures, such as one or more of the following: paralysis of cranial nerves; root pains; disturbances of pupillary, tendon and plantar reflexes; hemiplegia; aphasia; apraxia, and finally dementia, particularly in younger persons when coupled with signs which suggest organic involvement of the brain. An observation made in 1814 by Esquirel is still helpful: "In dementia a tremor of the lips is a fatal sign." Examination of the spinal fluid is most helpful in establishing the diagnosis of dementia paralytica and as a guide in the proper use of treatment by malaria. In multiple sclerosis, marked changes in the spinal fluid are usually adequate grounds for instituting active treatment, such as administration of typhoid vaccine. When mental and cerebral symptoms are accompanied by fever of obscure origin, spinal puncture usually is justified.

Comatose states occasionally present knotty problems in diagnosis. A glance at the spinal fluid may reveal the cause. The spinal fluid of patients who have syphilis should be examined within six months of the onset of the disease. A norm for these patients is thus established. Subsequent punctures should be made to determine whether the disease has invaded the nervous system, and, if it has, to determine the trend of the disease.

---

*From the Section on Neurology, The Mayo Clinic, Rochester, Minn. Read before the Minnesota State Medical Association, Minneapolis, May 5, 1931.

In transverse lesions of the spinal cord, roentgenographic study usually provides any reason there may be for not examining the spinal fluid. Complete data, particularly the character of the response on jugular compression, and estimation of the content of protein, should be made; otherwise the puncture may have to be repeated. In fracture of the spinal column if displacement is not so great that section of the cord is a foregone conclusion, demonstration of subarachnoid block is of assistance in deciding whether or not laminectomy should be considered.

Any deviation from the usual course of sciatic neuritis, particularly bilaterally, is an indication for spinal puncture. A "dry tap" in the hands of a skilled technician usually means that a tumor has filled the canal.

The last reason for diagnostic puncture I shall merely mention, namely, that of injecting air or roentgenologically opaque mediums. The selection of cases for such procedures should be left to the expert, since the procedure may be harmful, and since special experience is required both in the doing of these tests and in interpreting the results.

It need hardly be said that spinal puncture is a method by which serums, anesthetics, various dyes, and salvarsanized serums are administered. Introduction of salvarsanized serums is usually indicated in treating asymptomatic syphilis, when other methods of treatment have failed.

A useful therapeutic procedure is spinal drainage. This is usually indicated in treatment of meningitis; it provides a means of removing blood from the subarachnoid space, and may be a valuable aid in the treatment of uremic coma, malignant hypertension, status epilepticus, and delirium tremens.

I have purposely refrained from numerous temptations to go afield in the consideration of this subject. The various indications I have cited so briefly are not all of the indications, and they are subject to exceptions. To perform a spinal puncture without having preceded it by neurologic examination is a mistake. The indications will occur to every physician if he will interest himself in neurologic diseases; he can often tell what is wrong with a patient's nervous system even though he cannot attach the orthodox and unessential name to the disease.

PRESIDENT'S LETTER

A RECENT Associated Press story reports that the mails are being deluged, these days, with advertising of quacks, cultists, and medical fakes. Postal authorities are seriously taxed to trace and bar the most flagrant offenders. Physicians certainly should be interested.

No doubt this unusual activity is a sign of the times. It may be that business is not so good as it might be with this infamous gentry. On the other hand and by the same token, it may be that business is thriving. Perhaps the gullible become more gullible instead of less in times of uneasiness and want.

It is a curious quirk every physician has had to reckon with that people who complain the loudest about the legitimate bill of a regular practitioner are likely to be the first to give cash in advance to a fake.

In any case, the presence of an epidemic of so grave a disease as poliomyelitis presents a serious complication in dealing with the quack problem.

In the face of an already established paralysis the physician can offer nothing immediate or spectacular in treatment or hope of recovery. Recovery will depend upon long, tedious, disheartening regimen with no certain prospect of full recovery at the end. And a whole school of fake healers has armed itself almost over night to take advantage of the situation.

For instance, a self-styled "clinic" with headquarters in a neighboring state is very thoroughly canvassing Minnesota sufferers from the disease just now. This clinic is composed of a half dozen men, none of whom is a registered physician. They operate an "institute" with their clinic and they draw an every-growing clientele in Minnesota and the Northwest. Some live within an hour's ride of the Eustis Hospital for Crippled Children at the University of Minnesota and of the Gillette State Hospital, among the finest institutes of their kind in the United States for the care of crippled children. Admittance to these institutions is free to those who cannot afford to pay. Needless to remark, admittance to this "clinic" and institute is not free nor even moderately priced for anyone, though the price in cash that victims must pay is of no importance at all beside the tragic price in hopelessly crippled bodies.

This criminal assault upon the ignorance and anxiety of the families of "polio" victims is much more smooth and insinuating than that of the blatant old fashioned fake. Nowadays Dr. "Curem" is head of a "famous clinic" and, no matter what the misused word "clinic" may mean to the profession, to the gullible public it conveys an idea of scientific mystery and professional repute. Furthermore, Dr. "Curem" says, in a vague grandiose manner, that he is a member of "many learned societies" and to the large number of persons who still do not understand the significance of a County Medical Society roster or an American Medical Association directory, that suffices.

The responsibility for combating this sort of thing rests upon the medical profession and with it, of course, the schools, the church and public health agencies. But the medical profession must lead.

In spite of its long and brilliant public service in improving and standardizing hospitals and medical education, organized medicine has still to educate the public on what it means to be a licensed physician.

The same public that demands certificates of a proper education from its teachers still accepts self-styled doctors without certificates for its healers.

It is a challenge, not only to the private well-being but to the public conscience of the licensed physician, and organized medicine must meet it.

L. Sogge

President,
Minnesota State Medical Association.

Vol. XIV November, 1931 No. 11

THE POLIOMYELITIS SITUATION

Minnesota is still in the midst of an epidemic of poliomyelitis which is almost nation-wide. The New England states and New York have especially suffered and Minnesota has had more cases in proportion to population than her neighboring states. The State Board of Health reports 636 cases with forty-three deaths this year up to October 15, thirty cases and six deaths having been reported the first six months of the year.

The epidemic first made its appearance in and around Duluth the last of July, although there were more than the usual number of sporadic cases in the state during the first half of the year. The following figures show that the epidemic reached its height at Duluth in August, at Saint Paul in September, and apparently somewhat later in Minneapolis.

	Duluth	Saint Paul	Minneapolis
July	11 (2)*		
August	44 (3)	38 (3)	21
September	29	120 (7)	25 (3)
October 1-15	5	30 (3)	25

*Bracketed figures represent deaths.

Scattered cases have been reported from all over the state, few counties having escaped. The weekly totals were higher the first week in October than many preceding weeks. From the standpoint of the appearance of first symptoms, however, it is quite probable that the peak of the epidemic in the state was reached about the first of October.

The mortality of the epidemic so far has been about 6 per cent and is lower than that for the sporadic cases reported during the first half of the year. The explanation may be in the fact that more mild cases are overlooked in the absence of an epidemic. It is not an unusual experience to elicit histories of illnesses which must have been mild attacks of the disease in other children of a family with perhaps one child paralyzed.

At this time it is impossible to state what percentage of the cases reported had no paralysis but it is safe to say it will be considerable. Muscle paralysis, or weakness, loss of or diminished reflexes are usually rather definite. Stiff neck, fever and increased cell count in the spinal fluid is generally recognized as indicative of the presence of poliomyelitis. There are certainly borderline cases which are impossible to diagnose.

The use of convalescent serum seems to be the only generally accepted specific method of treatment. Dr. McKinley's proposal for the wholesale immunization of children in the presence of an epidemic, the details of which were presented in an article in the October number of Minnesota Medicine, has attracted considerable attention. The technic outlined is rather impracticable, especially in the territory outside of the larger cities. Traveling units from the State Board of Health with the necessary equipment are expensive and the demand for such service would all come at about the same time.

It does seem as though a demonstration of the value of the method in selected smaller communities during a widespread epidemic would be decidedly worth while. If the results showed the production of a passive immunity of long enough duration and a simpler technic to be just as efficient, the method could be put into general use.

Some day the etiological organism in poliomyelitis will be discovered. Then the hope of prevention will lie in universal immunization through vaccination.

MORE HUMANISM IN MEDICAL SOCIETIES

We quote from the Valedictory Address of the retiring president of the Hennepin County Medical Society, Dr. Stephen H. Baxter, which appeared in the Bulletin of that Society of October 10:

> I would like to suggest that we put a little more humanism into our Society. It ought to be more than an organization to which we pay, under a certain amount of compulsion, certain dues; whose meetings we attend, in a perfunctory way, once a month. It ought to be a place where animosities can be broken down, jealousies forgotten, personalities overlooked,—where all can unite for the welfare of our profession, and in so doing we will best be serving our own personal interests and those of the public. In the direction of putting more humanism into the Society, I would like to have the scope of some committee (possibly the Entertainment Committee) enlarged so that one of its functions would be to make personal contacts, in the name of the Society, with members who are sick. According to our present practice, the names of members who are sick, and who may be permanently incapacitated, may be dropped from the rolls after receiving a certain number of notices of delinquency. True, members who are permanently disabled may "at their own request" become emeritus members, but who would want to be an emeritus member of a Society that took no cognizance of his misfortune except "at his own request"? Certainly, one of the functions of our Society, if it is to perform its full ethical obligation, is to show a little human interest in its members without waiting until they are totally and permanently disabled or are threatened with expulsion for non-payment of dues.
>
> I would suggest, also, that the names of members who have attained the required age and years of membership in the Society be automatically transferred to the list of emeritus members, and that a letter be sen to such members notifying them of this action and stating that it is done as a mark of honor in recognition of long service. Would this not be a friendly gesture toward our older members more becoming a Society like ours than to require that such recognition be given "at their own request"? Then let them continue as active members at their own request, which doubtless, some of them would elect to do.

The proposal is so well put that comments are rather superfluous.

A case in point. A physician died recently at the age of seventy-five, having been a member of his local county society some twenty-three years Perhaps because of ill health or declining practice or both his name was on the list for reinstatement since he had previously been suspended for failure to pay his dues. Before he was reinstated he died. A committee such as Dr Baxter suggests ought to have humanized his society relation a bit. Surely society membership should mean much more than the phrase in one's obituary notice, "He was a member of his local county society."

OUR ERROR

In the last issue of MINNESOTA MEDICINE the opinion was twice expressed (two errors) that the A. M. A. Directory might add to its value if more complete. The inquiry was made from headquarters—how? Upon careful investigation of the data given in the Directory and comparison with other directories, which, by the way, are few in numbers, we are forced to admit that the additional information contained in other directories, even at twice the price, is non-essential. One of these carries the list of scientific publications, undergraduate fraternities, et cetera, the inclusion of which in the already large A. M. A. Directory would be prohibitory.

We imagine that we were not alone in our lack of appreciation of the actually extensive amount of information about ourselves which this volume contains. The interpretation of the system of symbols employed is not very difficult but does require a little concentration. This method keeps the volume down to a manageable size. It contains information about all physicians who have been licensed and not just the best of us according to some layman's opinion. The data are as reliable as is humanly possible and are made up-to-date every two years.

Our apologies are tendered the editors of this remarkable volume and we admit we have no constructive criticism to make.

There—we feel better.

OBITUARY

Albert Kumpf

1901-1931

Dr. Albert Kumpf, formerly of Minneapolis, died Monday, October 12, at his home in Hot Springs, South Dakota.

Dr. Kumpf was born at New Hampton, Iowa, and had lived in Minneapolis for eleven years before making his home in South Dakota last year. He was a graduate of the medical school of the University of Minnesota and had served there as an instructor for three years after his graduation. He was a member of Alpha Omega Alpha, honorary fraternity, and of the Trinity Lutheran church.

Surviving are his wife, his parents, Mr. and Mrs. Louis Kumpf, and a sister, Elizabeth, all of Minneapolis.

Silas E. Brown

1856–1931

Dr. Silas E. Brown, 75 years old, a physician and surgeon in Saint Paul more than twenty years, died Saturday, October 10, 1931, at his home in Saint Paul after a brief illness. He died in active practice, as he wished. On the Wednesday preceding his death he gave medical testimony in court for an hour and had scheduled himself to see patients on the following four days.

Dr. Brown was born in Heuvelton, N. Y., February 24, 1856. He received his early education in local schools and at the Pottsdam, New York, Normal School. He began his medical studies at McGill College, Montreal, where he was a student under the famed Sir William Osler. He told of how Sir William used to make him and his fellow students shed their coats and go to work at the city morgue, lecturing as they performed autopsies. After his second year at McGill he transferred to New York University Medical School, where he was graduated in 1883.

For twenty-five years he practiced in Ogdensburg, N. Y. He was appointed by the United States government as marine surgeon and United States health officer in 1884, and coroner of St. Lawrence County in the same year. In these capacities he served for twenty-five years before moving to St. Paul. While in Ogdensburg he was also president of the St. Lawrence County Medical Society and of the Northern New York Medical Society. He was lecturer for the St. Lawrence State Hospital for the insane and examiner for various insurance companies. After moving to St. Paul he was appointed railway surgeon, and examiner for several insurance companies, was a member of the Minnesota Medical Society and the Ramsey County Medical Society. He was a Mason and an elder in the House of Hope Presbyterian Church.

Surviving are his widow, Mary Macon Brown, and two daughters, Josephine Brown of New York, staff secretary of the National Family Welfare Association, and Marion Brown MacLean of Milwaukee.

Soren P. Rees

1870-1931

Dr. Soren P. Rees, physician and surgeon, died Friday night, October 2, 1931, at his home, 1715 West Franklin avenue, in Minneapolis, following an illness of three months. He was 61 years old.

For a number of years Dr. Rees was a member of the faculty of the medical school of the University of Minnesota, and had been a member of the staff of Swedish hospital since that institution was founded. He was chief of medicine on the staff of General hospital for some time.

Dr. Rees was born September 27, 1870, at Vejle, Denmark. When a boy of eleven, he was brought to the United States by his parents, who established residence in Stillwater, Minn., in 1881.

He matriculated at the University of Minnesota in 1890, and entered the medical school in 1895, being graduated with the class of 1897. Until June of 1898 he served his interneship at St. Barnabas hospital. Dr. Rees completed one year of postgraduate work in Vienna. He then entered the practice of medicine at Anoka, Minn. In 1901 he moved to Minneapolis and opened an office. While a student at the university, he was assistant registrar under E. Bird Johnson. When later he became a member of the faculty he gave instruction in physical diagnosis.

Dr. Rees earned his own living while attending both high school and the university and was graduated with honors as a member of Phi Beta Kappa, national honorary scholastic fraternity, and the medical fraternity of Phi Beta Pi. He also was a member of Theta Delta Chi, national academic fraternity, of which he was a charter member at Minnesota.

Dr. Rees was a member of the Hennepin County Medical Society, the Minnesota State Medical Association, the Minnesota Academy of Medicine and the American Medical Association.

Aside from his professional work he was interested in the fine arts. He was a life member of the Minneapolis Institute of Arts, and was a founder and secretary of the Scandinavian Art Society of America. He was a deacon of Trinity Baptist church.

Surviving him are his wife, Estelle Crocker Rees, whom he married in 1898; a son, Douglas, and a sister, Mrs. Clara Anderson, of Stillwater.

A FORUM OF THE COMMITTEE ON PUBLIC HEALTH EDUCATION

The energy and ambition of the Women's Auxiliary to the State Association is obvious in the very complete and thoughtful supplement now under discussion in Minnesota to the Official Health Program of the Women's Auxiliary to the American Medical Association.

Where the national program, outlined on this page last year, indicated broadly the part of the Auxiliary in the important business of Public Health Education, this state supplement is specific and definite. Minnesota women propose to know with great minuteness the problems of the medical profession in this state and their own part in solving them. If the study is carried on as intelligently as it is begun in this outline, women of the auxiliary should be better equipped than many of the physicians whose problems they are studying to assist with the business of public health education by the physician.

Following are the high points in this outline:

THE COMPONENT AUXILIARY:

1. County Medical Society Advisors
2. Joint Meetings
3. Joint Programs

STATE HEALTH RELATIONS:

Dangers of State Medicine
1. In Other Countries—Europe-Canada, U. S.
2. Legislation leading to
   Current Literature
   Cost of Medical Care
   (a) Physician
   (b) Nurse
   (c) Patent Medicine
   (d) Laboratories
   (e) Druggists
   (f) Health Insurance
3. Public Health
   (a) State
   (b) County
   (c) City Dept.
   (d) National Committee
   (e) County Health Unit
   (f) School Nurse
   (g) School Health
4. Relation of County Medical Society and Its Members

PUBLIC HEALTH EDUCATION:

1. Official and Voluntary Health Agencies
2. Contact with Lay Health and Civic Organizations
3. Immunization
   (a) Minnesota Plan
   (b) In other States
      (1) Smallpox
      (2) Vaccination
      (3) Diphtheria
         (a) Our campaign
4. Pre-school Child Examinations
5. Parent-Teacher Associations
   (a) Purpose and Plan
6. Examination Given by Family Physician
7. Follow-up for Correction of Remediable Defects
8. Health Campaigns:
   (a) Heart
   (b) Tuberculosis
   (c) Crippled Children, etc.
9. Period Health Examinations:
   (a) Every Member Should Have an Annual Physical Examination
   (b) Importance of Early Discovery of Disease:
      (1) Cancer
      (2) Heart
      (3) Tuberculosis, etc.
10. Medical Ethics
   (a) The Medical Society and Auxiliary
   (b) The Physician
   (c) The Physician's Wife
11. Medical Legislation
   (a) National:
      (1) Jones-Cooper Bill
      (2) Sheppard-Towner
      (3) Vivisection
      (4) Cultists
      (5) State Basic Science Law
      (6) New Medical Practice Act, etc.
      (7) 1931 Recommendations for Northwest Regional Conference.

As Auxiliary members we should be interested in the following topics, and study them—

STATE BOARD OF CONTROL:

1. Its Functions?
2. Institutions
   (1) Insane Asylums
   (2) School for Feeble Minded—Faribault
   (3) School for the Deaf—Faribault
   (4) School for the Blind—Faribault
   (5) Colony for Epileptics at Cambridge
   (6) Training School at Red Wing
   (7) Home School for Girls—Sauk Center
   (8) Public School—Owatonna
3. Tuberculosis:
   Dr. Arnold S. Anderson, Secretary of the Tuberculosis Division, State Board of Control, is available for talks, as are also the various superintendents of the Tuberculosis Sanatoria in the different parts of the State.
4. Crippled Children:
   The Gillette Hospital for Crippled Children in St. Paul also comes under the State Board of Control, and members of its staff are available for talks.
   In addition there is the Shrine Hospital for Crippled Children and also the Eustis Hospital in connection with the University of Minnesota.
   The Crippled Child is receiving much attention from many lay groups. Have you made a study of legislation pertaining to crippled children, also a survey of institutions caring for the crippled child. You may find the subject of vast interest and be

able to do much better work for your clubs and Parent-Teacher Associations if you study the problem from the standpoint of the State Medical Association and the Auxiliary.

MINNESOTA STATE BOARD OF HEALTH:

1. Personnel? How Selected?
2. Functions:
   What help should a rural community naturally expect from our State Board of Health?
   (1) Pure Milk Program
      (a) Laws Governing the Handling of Milk in Minnesota
      (b) What is Certified Milk?
      (c) What is Pasteurized Milk?
      (d) Do You Know the Story of Tuberculosis Testing of Cows in Minnesota?
   (2) Sanitation Laws?
   (3) Water Supply Laws?
   (4) Communicable Disease Laws?

UNITED STATES PUBLIC HEALTH SERVICE:

1. Personnel? How Selected?
2. Functions?
   (a) What Help in Auxiliary Work?
   (b) What is the U. S. Veterans Bureau?

MINNESOTA PUBLIC HEALTH ASSOCIATION:

1. Personnel? How Selected?
2. Duties:
   (a) What Help in Auxiliary Work?

MINNESOTA STATE MEDICAL ASSOCIATION:

1. Personnel?
2. Duties of Committees?
   (a) Many Doing Specific Line of Work.
   (b) Of General Interest to Auxiliary Workers are:
      (1) Committee on Hospitals and Medical Education
      (2) Committee on Public Policy and Legislation
      (3) Committee on Public Health Relations and Education
      (4) Committee on State Health Relations
      (5) Heart Committee
      (6) Committee on Public Health Nursing

The Committees of importance to the Auxiliary under the Minnesota State Medical Association are listed above, and the Chairmen would be happy to explain to the Auxiliaries the functions of their committees.

The office personnel of the Executive Secretary of the Minnesota State Medical Association and the Minnesota Public Health Association at 11 West Summit Avenue, St. Paul, under the personal supervision of Dr. E. A. Meyerding, is ready at all times to help you get your program problems in shape. They will help you select speakers, reading material, and helps of many kinds, on all topics in the foregoing outline.

If as an Auxiliary you meet at the same time as your County Medical Society, it would be wise to select a program chairman from your group, to keep in touch with the program chairman from the Medical Society, and plan to have the speaker for the Doctors' program give the Auxiliary some time, asking him to give you a definite topic. This time can very easily be arranged for while the Medical Society is holding its business meeting.

Many Auxiliary groups are taking topics from *Everybody's Health*, *Hygeia*, and MINNESOTA MEDICINE, asking members to review them, with an open discussion following.

Dr. Meyerding has a number of books in his office library that would make excellent books to review for Auxiliary programs and folders on three hundred subjects suitable for health talks, are on file. Upon request, material will be loaned to members of the Auxiliary.

FEDERAL SCIENTISTS TELL HEALTH ASSOCIATION OF RECENT FINDINGS

Oranges produced by trees sprayed with lead arsenate not only differ in chemical composition from normal oranges, but suffer a considerable loss of Vitamin C content which is regarded as such a highly desirable constituent of oranges, Dr. E. M. Nelson and Mr. H. H. Mottern of the Bureau of Chemistry and Soils, U. S. Department of Agriculture, recently told members of the American Public Health Association in session at Montreal.

Doctor Nelson's statement followed completion of a series of experiments in the Bureau of Chemistry and Soils which have demonstrated that, besides causing a considerable loss of the valuable Vitamin C, spraying orange trees with lead arsenate reduces the acidity of the juice and decreases the sucrose with a corresponding increase in invert sugar. The principal orange producing States have laws prohibiting the use of arsenical sprays on this crop.

The spraying of oranges with lead arsenate involves no danger from arsenic poison, according to the findings of the bureau, which disclosed no arsenic in the edible portion of the orange following many applications of spray to orange trees.

Another interesting fact brought out by the recent investigation of the Department of Agriculture's chemists which Doctor Nelson announced today is that the processing of oranges, by the heat method of the department's Plant Quarantine and Control Administration, to destroy larvæ of the Mediterranean Fruit Fly during the recent eradication campaign against that pest did not change the character of the sugars, citric acid, or Vitamin C content of the fruit.

OF GENERAL INTEREST

A son, James Elwyn, was born to Dr. and Mrs. Elwyn V. Strand, Bayport, Minnesota, on August 16, 1931.

Dr. George E. Malmgren, formerly with the Mayo Clinic, has moved to Los Angeles, where he will practice proctology.

Dr. B. R. Kirklin of Rochester was elected first vice-president of the American Roentgen Ray Society at its recent meeting held in Atlantic City.

Dr. and Mrs. Chester M. Carlaw, Minneapolis, have returned from Montreal, where Dr. Carlaw attended the fortieth reunion of his class at McGill University.

Paul H. Fesler, Superintendent of the University of Minnesota Hospital, was installed as president of the American Hospital Association at its meeting in Toronto, October 2, 1931.

Doctor Russell M. Wilder has resigned his position as Professor of Medicine at the University of Chicago to join the staff of the Mayo Clinic and the Faculty of the Mayo Foundation Graduate School of the University of Minnesota as Professor of Medicine.

Dr. Arthur C. Strachauer and Dr. William R. Jones announce the opening of their offices on October 1, 1931, at 350 Medical Arts Building, Minneapolis, for the practice of general surgery. Dr. Strachauer has recently been appointed Chief Surgeon of the Soo Line Railway.

Dr. Strachauer has returned from the annual meeting of the directors of the American Society for the Control of Cancer, which was held in New York City October 10 to 14; also the annual meeting of the Conference on Cancer Clinics of the American College of Surgeons.

The new Bethesda hospital, Saint Paul, is well on the way toward completion. The $500,000 building on Capitol Avenue, between Como Avenue and Viola Street is being erected on a hill and will tower high in the air so that it can be seen for miles. No definite date has been set for completing the building.

The Clarkfield Community Hospital, Clarkfield, Minnesota, was dedicated Sunday afternoon, September 27, with appropriate exercises. The building was erected at a cost of $15,000 and contains fifteen rooms. Dr. Malvin I. Hauge and Dr. M. M. Hauge of Clarkfield are members of the staff of the hospital.

Kappa Phi chapter of Phi Chi, national medical fraternity, has just opened a new $40,000 fraternity house at 325 Harvard Street S. E., Minneapolis, for undergraduate members at the University of Minnesota. The building, of the English town house type, was designed by C. P. Pesek. The exterior is of skintled brick with Bedford trim. The Fraternity held an open house in October.

Award to a former St. Paul physician of a gold medal emblematic of first place in a medical essay contest and a cash prize of $500 was announced Saturday by the Association of Military Surgeons.

The winner is Colonel George A. Skinner of the Army Medical Corps, stationed at the Seventh Corps Area Headquarters in Omaha. The contest, conducted by the association, was for essays on "The Influence of Epidemic Diseases on Military Operations in the Western Hemisphere."

Twenty-four hospitals of the Twin Cities have met the standards required for full approval by the American College of Surgeons, it was announced October 12, by Dr. Franklin H. Martin, director general of the college, at the opening session of the twenty-first annual clinical congress of surgeons in New York.

Of the twenty-four fully approved institutions thirteen are Minneapolis institutions, and eleven are in St. Paul. The Minneapolis hospitals placed on the list are Abbott, Asbury, Eitel, Fairview, Hill Crest, Lutheran Deaconess, St. Mary's, Shriners' Hospital for Crippled Children, Maternity, Minneapolis General, Northwestern, University and Veterans.

St. Andrews, St. Barnabas and Swedish hospitals, Minneapolis, have been placed on the list as having accepted the minimum requirements laid down by the American College of Surgeons.

St. Paul hospitals fully approved are Ancker, Bethesda, Miller, Children's, Gillette Hospital for Crippled Children, Midway, Mounds Park, Northern Pacific, St. John's, St. Joseph's and St. Luke's.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

LAWYER ARRESTED FOR ALLEGED VIOLATION OF BASIC SCIENCE LAW

State of Minnesota *vs.* John Hugh Lally

On September 14, 1931, a complaint was filed in the Municipal Court in Minneapolis alleging that one John Hugh Lally had practiced healing without a Basic Science Certificate.

The defendant in this case is a lawyer licensed in the State of Illinois who has been touring the country giving health lectures and claiming to be engaged in spiritual healing.

Lally was held to await the action of Grand Jury by Judge Wright of the Municipal Court. Following a preliminary hearing his bail was set in the sum of $1,250. Following Lally's arraignment in District Court, where he entered a plea of not guilty, a motion was made by the defendant to quash the information against him.

On September 28, the date set for the trial, counsel for the defendant informed the Court that Lally had left for Detroit, Michigan.

Judge Guilford ordered the defendant's bail forfeited and a bench warrant issued for his arrest.

Lally has been previously convicted of violating the Medical Laws in Chicago, Illinois, and Winnipeg, Manitoba, Canada.

MINNEAPOLIS WOMAN FINED ONE HUNDRED DOLLARS FOR VIOLATING BASIC SCIENCE LAW

State of Minnesota *vs.* Mayme F. White

On September 25, Mayme F. White, 61 years of age, unlicensed, and living at 512 Forest Ave., Minneapolis, entered a plea of guilty to practicing healing without a Basic Science Certificate before the Honorable Horace D. Dickinson, Judge of the District Court. Mrs. White claimed that she was a Spiritualist and had been practicing magnetic healing. However, in the present case, roots and herbs and some pills had been prescribed for the patient. Judge Dickinson imposed a fine of $100 or ninety days in the Minneapolis Work House, with the defendant paying the fine. The Court also warned the defendant against violating the medical laws in the future. The Court instructed the defendant that the practice of healing was regulated by law and required a license and that she undoubtedly would be prosecuted with more serious consequences for a second violation. The records in the Probate Court disclose that Mrs. White had filed a claim against an estate in the sum of $167 for services, but the claim was not allowed by the Court.

NEW AND NON-OFFICIAL REMEDIES

The following products have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in New and Non-official Remedies:

Abbott Laboratories
- Neocinchophen-Abbott Tablets, 7½ grains

Lederle Laboratories, Inc.
- Diphtheria Toxoid, two 1 c.c. syringe packages
- Diphtheria Toxoid, two 1 c.c. vial packages
- Diphtheria Toxoid, one syringe package
- Diphtheria Toxoid, one vial package
- Solution Liver Extract Parenteral (Lederle)

E. R. Squibb & Sons
- Diphtheria Toxin for the Schick Test, Ready to Use without Dilution
- Scarlet Fever Streptococcus Toxin-Squibb, six 10 c.c. vial packages
- Squibb Liquid Petrolatum with Agar and Phenolphthalein

Pentobarbital-Sodium — Sodium ethyl (1-methylbutyl) barbiturate. Sodium ethyl (methylpropylcarbinyl) barbiturate. The monosodium salt of ethyl-(1-methylbutyl) barbituric acid. Pentobarbital-sodium differs from barbital, U.S.P. (sodium diethylbarbiturate) in that one of the ethyl groups of the latter is replaced in the former by a 1-methylbutyl group. The actions and uses of pentobarbital-sodium are essentially similar to those of barbital, but it is effective in smaller doses. The action is of relatively brief duration, which may constitute an advantage, especially when relatively large doses are administered. It is used as a sedative, particularly prior to local, general or spinal anesthesia. It can be used safely for such purposes only by those who have had adequate experience and who are familiar with the literature concerning such use. The drug may be administered by mouth or rectum; intravenous injection is considered unsafe.

Capsules Pentbarbital-Sodium-Abbott, 1½ grains.—Each capsule contains pentobarbital-sodium-N.N.R., 0.1 Gm. (1½ grains). Abbott Laboratories, North Chicago, Ill.

Pulvules Pentobarbital-Sodium-Lilly, 1½ grains.—Each pulvule (capsule) contains pentobarbital-sodium-N.N.R., 0.1 Gm. (1½ grains), and starch, 0.13 Gm. Eli Lilly & Co., Indianapolis, Ind. (Jour. A. M. A., September 5, 1931, p. 705.)

Skiodan.—Methiodal.—The sodium salt of mono-iodo-methane-sulphonic acid. Skiodan contains 52 per cent of iodine. It is proposed as a therapeutically indifferent medium for roentgenography, especially for visualization of the urinary tract, either by intravenous injection or by direct injection into the renal pelvis through a ureteral catheter. It has also been administered rectally. Winthrop Chemical Co., Inc., New York.

Gynergen Solution 0.1 Per Cent.—Each c.c. of solution contains 1 mg. of gynergen (New and Non-official Remedies, 1931, p. 183) and a small excess of tartaric acid. Sandoz Chemical Works, Inc., New York.

Squibb Chocolate Vitavose.—A mixture of Squibb's vitavose (New and Non-official Remedies, 1931, p. 245) 30 per cent, with cocoa, milk solids and sucrose. E. R. Squibb & Sons, New York. (Jour. A. M. A., September 12, 1931, p. 779.)

Scarlet Fever Streptococcus Toxin-Squibb (New and Non-official Remedies, 1931, p. 370).—This product is also marketed in packages of six 10 c.c. vials of toxin containing, respectively, 500, 2,000, 8,000, 25,000, 40,000 and 40,000 skin test doses per c.c. E. R. Squibb & Sons, New York. (Jour. A. M. A., September 26, 1931, p. 930.)

CONSULTATION BUREAU

WM. A. O'BRIEN, M.D., *Director*
Minnesota State Medical Association
11 West Summit Avenue
Saint Paul, Minnesota

1. *Question.*—Please give me some information concerning the present conception of the cause, diagnosis, treatment, and prognosis of hay fever. Many of my patients have asked me about the possibilities of preventing next year's attacks. I would, also, like to know something about perennial desensitization.

Answer.—Both hay fever and asthma are manifestations of a hypersensitiveness to some foreign substance. At the present time, there is a widespread and critical interest in these conditions. This has greatly increased our knowledge of these diseases and has led to marked improvement in treatment. Both are manifestations of what has been variously termed anaphylaxis, allergy, atopy, idiosyncrasy, and the phenomena of hypersensitiveness.

Hay fever is a symptom-complex characterized by red eyes, obstructed nose, paroxysmal sneezing, and nasal discharge of a watery secretion which occurs each year at a definite season and depends upon the fact that the patient is hypersensitive to the pollen of one or more plants which blossom at that time. Allergic coryza is a less specific term, which is ordinarily applied to those patients whose symptoms are not necessarily limited to the summer months but are due to other irritants. Perennial hay fever or chronic vasomotor rhinitis resembles hay fever but is due to a different cause.

Hay fever was the first of the manifestations of allergy to be recognized. It has been known for some time that plant pollens are responsible. The most characteristic feature of hay fever due to pollens is the time of the attack each year. The precise seasons vary with the vegetations of various parts of the country. The usual complaints are located in the nose and eyes. Other symptoms equally characteristic are intense itching of the palate and fauces, a reddish eruption in the mouth, difficulty in swallowing, ear disturbances, including deafness, and asthma. The latter may be considered as an extension of the hay fever process when it occurs only in conjunction with the former disease. It is important to remember that occasionally only isolated features of the hay fever syndrome are present. The seasonal association of even one of these symptoms may be significant.

Pollen is the germ cell of the male plant. Ordinary flowering plants, because of time factors, seldom show self-pollination. Cross pollination is usually effected by insects, birds, and the wind. Ragweed usually has separate male and female plants, the males being more numerous. Most of the grasses and weeds are wind pollinated. Weather has a very important effect upon the concentration of the pollen in the air—rain frees the air of pollen but it makes the weeds grow, and when the sun comes out more pollen than ever is produced. Hay fever is always milder in rainy, cloudy weather. Wind usually increases the symptoms. Patients are usually better in the city than in the country. In any attempt to enforce weed laws, this factor is very important.

Before attempting to get any assistance from the patient's history as to the pollen factor, it is necessary to know the time of pollination in Minnesota. As a general rule, the trees are responsible for the earlier attacks, the grasses for the midsummer disease, and the weeds, notably the ragweed, for the late summer and early fall attacks. Patients frequently state that their hay fever begins on the same date each year. This is of great assistance in making a specific diagnosis. It is interesting that ragweed does not occur in Europe. Travelers returning from abroad during the hay fever season frequently have their first attacks some distance out at sea because of air currents out from shore. Certain sections of the United States are free of ragweed and are sought by sufferers on this account.

There are two ways of finding out the etiology of pollen-sensitive patients, one by skin tests and the other by history. The patient should be treated for that particular pollen which is causing his symptom. Crossed reactions are frequent and skin tests may be positive when the patient is not sensitive. At the present time, no definite method of selection of the proper pollen is satisfactory. Close immunological relationships occur between various grasses and between various weeds. Immunization against one may be effective against others. All of these points are very confusing at the present time and make specific treatment rather difficult. Both pre-seasonal and co-seasonal treatment offer relief.

Symptomatic treatment (nonspecific) includes direct cauterization of the mucous membrane, sprays of adrenalin and ephedrin, cocaine, eye astringents, and general measures. Other drugs which have been used are bromides, acetylsalicylic acid, nitrohydrochloric acid, sodium bicarbonate and ephedrin by mouth, and local applications of radium or X-ray in small doses to the eyes and nose. There is such a great variability in the individual reactions of patients that treatment should be used accordingly. Many milder forms do not require specific treatment. There is a large group, seriously disabled by the disease, and for them specific therapy is not a question of choice but a necessity.

Allergy is usually a hereditary affliction. Very little can be done about this. Dust-free rooms may be developed and are said to be useful. Even a few hours, freedom may induce comfort for the entire day. Some sufferers spend a few hours daily in cold storage plants. The temperature is probably not as important as the poor ventilation in giving relief. Others wear masks. Desensitization is the process by which the reaction of the patient to the defending substance is modified. No treatment could be successful unless the extract used is made from the particular substance responsible. Subcutaneous serial injections are made usually about six to ten weeks before the expected time of appearance. The size of the first dose is based upon the tolerance. The number of doses and the interval

(Continued on page 1019)

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

MEDICAL BROADCAST FOR THE MONTH

The Minnesota State Medical Association Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 11:15 o'clock every Wednesday morning over Station WCCO, Minneapolis and Saint Paul (810 kilocycles or 370.2 meters).

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota.

The program for the month of November will be as follows:

November 4—Fracture of Skull.
November 11—What are the Psychoneuroses?
November 18—Prevention of Eye Strain.
November 25—Treatment of Leukemia.

MINNESOTA SOCIETY OF INTERNAL MEDICINE

The semi-annual meeting of the Minnesota Society of Internal Medicine will be held in the Ramsey County Medical Society rooms in the new Lowry Building, Saint Paul, November 1, 1931.

The session begins at 9 a. m. and will be followed by dinner at 6 p. m. at the Town and Country Club, Saint Paul.

Symposia on "Chronic Arthritis" and "Angina Pectoris" are included in a most interesting program.

ASSOCIATION OF RESIDENT AND EX-RESIDENT PHYSICIANS OF THE MAYO CLINIC

Dr. Edgerton L. Crispin of Los Angeles was named president of the Association of Resident and Ex-resident Physicians of the Mayo Clinic and Mayo Foundation at Rochester, Minnesota, Friday, October 9, 1931.

Other officers named are Dr. Clyde Roeder of Omaha, first vice president; Dr. Frank E. McEvoy of Providence, R. I., second vice president; Dr. Thomas J. Kinsella of Oak Terrace, Minn., secretary; Dr. Porter P. Vinson of Rochester, associate secretary and treasurer.

Dr. D. F. Hollenbeck of Rochester was elected to the board of governors, succeeding Dr. Herbert Z. Griffin of Rochester. Other governors are Dr. Frank C. Mann and Dr. Willis S. Lemon, both of Rochester.

Five new members of the advisory board elected are: Dr. L. D. Powell of Des Moines; Dr. Robert E. Moran of Washington; Dr. Carl R. Steinke of Akron; Dr. Eric Larson of Los Angeles, and Dr. Bernard McGrath of Milwaukee.

LYON-LINCOLN COUNTY MEDICAL SOCIETY

At a meeting of the Lyon-Lincoln County Medical Society held Tuesday, October 6, at Marshall, Minn., the following officers for 1932 were elected: President, Dr. C. M. Golden, Tyler; vice president, Dr. Archibald Olson, Hendricks; secretary-treasurer, Dr. H. M. Workman, Tracy; delegate to state meeting, Dr. E. T. Sanderson, Minneota; alternate, Dr. A. L. Vadheim, Tyler; censor for three years, Dr. P. E. Hermanson, Hendricks.

The Society is holding a very successful Clinical Course.

RICE COUNTY MEDICAL SOCIETY

Rice County Medical Society met Tuesday, September 29, at 7:45 P. M., in the Faribault Clinic rooms.

Dr. Waltman Walters, of the Mayo Clinic gave a lecture on "Surgical Aspects of Obstructive Jaundice."

C. J. Plonske, Secretary.

SOUTHWESTERN MINNESOTA MEDICAL ASSOCIATION

Dr. C. A. Slater, superintendent of the Southwestern Minnesota Tuberculosis Sanatorium at Worthington, was named president of the Southwestern Minnesota Medical Association at a meeting held in Slayton, October 10.

Dr. J. T. Rose of Lakefield is the new vice president and Dr. W. E. McKeown of Pipestone was re-elected secretary-treasurer.

ST. LOUIS COUNTY MEDICAL SOCIETY

At the annual meeting of the St. Louis County Medical Society held recently election of officers resulted as follows:

President, Norven H. Gillespie, Duluth; first vice president, Franklin Raiter, Cloquet; second vice president, O. L. McHaffie, Duluth; secretary-treasurer, M. McC. Fischer, Duluth.

Censors: Dr. A. E. Olson, Duluth; Dr. L. L. Merriman, Duluth; G. C. MacRae, Duluth.

Delegates: Dr. C. L. Haney and Dr. F. J. Elias, Duluth. Alternates: Dr. W. G. Strobel, Dr. W. N. Graves, Dr. Robert S. Forbes, and Dr. L. A. Barney, all of Duluth.

M. McC. Fischer, M. D., *Secretary.*

STEARNS-BENTON COUNTY SOCIETY

The regular meeting of the Stearns-Benton County Medical Society was held in Sauk Rapids, September 24, 1931. Dr. H. B. Clark gave a talk on the "Treatment of Syphilis"; Dr. F. J. Schatz reported five cases of Intestinal Obstruction in Infants; and Dr. F. H. Stangl discussed the "Uses of the Drinker Respirator."

Wm. H. Rumpf, M.D., *Secretary.*

WASHINGTON COUNTY SOCIETY

The regular monthly meeting of the Washington County Medical Society was held in Stillwater on September 8, 1931. The business part was taken care of during and after dinner, after which one of our own members, Dr. Carnot H. Sherman, gave an instructive talk. Dr. Sherman has just returned from Philadelphia where he spent two years at the Post Graduate School, Medical Department, University of Pennsylvania, where he received a diploma as Master of Medical Sciences in Surgery at his graduation, and also captured the place of honor in the class.

The Doctor described the work laid out for the students at this school, the only one in the country barring the Medical Department of the University of Minnesota, that gives advanced degrees in the specialties. The doctor also spoke on new methods of medication and diagnosis, especially emphasizing new ways of lessening error of diagnosis in interpretation of abdominal pains.

It was all very enjoyable and we are glad to have Doctor Sherman with us again.

E. Sydney Boleyn, *Secretary.*

WRIGHT COUNTY SOCIETY

The Wright County Medical Society held its third quarterly meeting at Delano, Minnesota, July 23, 1931, at 3:00 P. M.

Minutes of the October meeting, 1930, the January and April meetings, 1931, were read and accepted except for some corrections added to the minutes of the April meeting.

Dr. J. W. Olson of Cokato was accepted as a member of the Society. In the absence of the president, Dr. Klaveness of Saint Paul occupied the chair. Dr. Klaveness also made a report to the society about the proceedings of the House of Delegates.

Dr. Wangensteen of the University was the main speaker and gave a very interesting and instructive talk concerning "Diagnosis and Treatment of Intestinal Obstruction," illustrating his talk with lantern slides and charts.

A very profitable meeting.

C. L. Roholt, *Secretary.*

RED RIVER VALLEY MEDICAL SOCIETY

The Fall meeting of the Red River Valley Medical Society was held at the Hotel Evelyn in Thief River Falls, Tuesday, October 6, starting with a luncheon at 1 o'clock. The program, devoted to the newer phases of tuberculosis, was as follows:

"Discussion of Certain Phases of Tuberculosis," Dr. J. A. Myers, Minneapolis; Dr. E. A. Meyerding, Saint Paul; et al.

"Rectal Difficulties in the Tuberculous," Dr. Walter Fansler, Minneapolis.

Presentation of cases by members.

B. L. Oppegaard, M.D., *Secretary.*

PARK REGION MEDICAL SOCIETY

At a recent meeting of the Park Region Medical Society Dr. M. W. Kemp was elected president; Dr. O. V. Johnson, vice-president; Dr. E. A. Heidberg, secretary-treasurer. Dr. A. J. Lewis of Henning was chosen delegate to the state convention in Minneapolis.

NORTHWESTERN PEDIATRIC SOCIETY

The Fall meeting of the Northwestern Pediatric Society was held in Duluth on Saturday, October 10, 1931.

Dinner was served at the Kitchi Gammi Club at 7:00 p. m., followed by the scientific program at St. Luke's Hospital as follows:

1. a. "Scleroderma Neonatorum."
   b. "Agranulocytosis." Case reports.
   Dr. C. H. Schroder, Duluth.
2. "Pneumothorax; Probable Cyst of the Lung." Case Report.
   Dr. C. O. Kohlbry, Duluth.
3. "Eosinophilia with Splenomegaly." Case Report.
   Dr. O. W. Rowe, Duluth.
4. "Hypertension in Children and Its Effect on Eyesight."
   Dr. A. W. Graham, Chisholm.
5. "Meckel's Diverticulum: Report of a Case of Perforation."
   Dr. R. E. Nutting, Duluth.
6. "Latent Tetany of the Newborn."
   Dr. H. A. Sincock, Superior.
7. "Breast Feeding of the Newborn."
   Dr. C. A. Scherer, Duluth.

Alexander Stewart, *Secretary.*

WOMEN'S AUXILIARY
Minnesota State Medical Association

President—Mrs. James Blake, Hopkins
Chairman Press and Publicity—Mrs. Glen R. Matchan, Minneapolis
Editor—Mrs. Horatio B. Sweetser, Jr., Minneapolis

WASHINGTON COUNTY AUXILIARY

The Woman's Auxiliary to Washington County Medical Society was hostess at a bridge party, Tuesday, September 29, for the benefit of the Lakeview Memorial Hospital. Mrs. S. S. Hesselgrave, past state president; Mrs. James Blake, state president; Mrs. Edward Schons, of St. Paul, president-elect; and Mrs. W. H. Hengstler, president of the Ramsey County Auxiliary, were guests.

EASTERN MINNESOTA AUXILIARY

The doctors' wives from the Central Minnesota and Chisago-Pine County Medical Societies were invited to accompany their husbands to a dinner meeting at Cambridge, Thursday, September 17. With the assistance of Mrs. Hesselgrave, past state president, the women organized an auxiliary to the new Eastern Minnesota Medical Society. The following officers were elected: President, Mrs. H. C. Cooney, Princeton; vice president, Mrs. Charles Swenson, Braham; secretary-treasurer, Mrs. H. J. Kooiker, Milaca.

BLUE EARTH COUNTY AUXILIARY

Dr. E. A. Meyerding addressed the women of the Blue Earth County Medical Society Auxiliary at Mankato, October 5. He gave an interesting talk on the duties of auxiliary members. The auxiliary meeting was held concurrently with the doctors' meeting, and the two groups joined for a buffet luncheon.

WRIGHT COUNTY AUXILIARY

The annual meeting of the Wright County Medical Auxiliary was held October 6 at the home of Dr. and Mrs. Catlin at Buffalo. The meeting was called at four o'clock, and the work of the auxiliary discussed. Mrs. F. E. Ellison of Monticello was elected president, and Mrs. J. J. Catlin secretary and treasurer. A buffet supper was served.

RICE COUNTY AUXILIARY

The first annual meeting of the Rice County Auxiliary was held at Faribault, Wednesday, October 14, and took the form of a benefit bridge luncheon at the Hotel Faribault.

WEST CENTRAL AUXILIARY

On October 14 the West Central Medical Auxiliary held a dinner meeting at Morris. Dr. Emil Geist addressed the members.

STEELE COUNTY AUXILIARY

The Woman's Auxiliary of Steele County met at Owatonna, October 16, at the home of Mrs. E. W. Senn. Mrs. James Blake, state president, presented her program for the coming year.

BLUE EARTH VALLEY AUXILIARY

On October 8 the wives of the members of the Blue Earth Valley Medical Society met at dinner at the Hotel Constance for the purpose of forming an auxiliary. Mrs. Blake and Mrs. Hesselgrave were present and the following officers were elected: President, Mrs. R. C. Farrish, Sherburn; vice president, Mrs. A. J. Henderson, Kiester; secretary-treasurer, Mrs. H. B. Bailey, Fairmont.

RED RIVER VALLEY AUXILIARY

A dinner meeting of the Red River Valley Medical Auxiliary was held at Thief River Falls, October 6. Dr. Meyerding and Mrs. Hesselgrave were the speakers.

PROGRESS

Abstracts to be submitted to Section Supervisors.

Members are urged to abstract valuable articles which they run across in their reading and send the abstracts to the physicians in charge of the respective sections. In order to avoid duplication it would be well to communicate with one of the section supervisors before the article is abstracted.

SECTION SUPERVISORS

EYE, EAR, NOSE AND THROAT

EYE, EAR, NOSE AND THROAT

THE OCCURRENCE OF EYE LESIONS IN TUBERCULOUS PATIENTS: W. V. Moore (Am. Jour. Oph., 1931, Vol. 14, July, p. 596). Tuberculous eye lesions are rarely found among patients under treatment for active pulmonary tuberculosis. When patients with definite tuberculous eye lesions are thoroughly examined quiescent or healed lesions are frequently found in the lungs, tracheo-bronchial and hilus lymph glands. These primary foci may not produce constitutional symptoms, but are capable of discharging a few attenuated organisms into the circulation. It is probable that both the organisms and their toxic products may have some influence in producing lesions.

Finoff reported ocular tuberculous lesions of a severe and progressive type in rabbits following tubercle bacilli injected into the carotid; dead bacilli injected produced similar lesions but of a chronic course, resulting in scar formation.

Stark believed the foci too trifling in nature to produce enough toxin to stimulate antibody development, the bacilli having become attenuated and less virulent than those producing the initial lesion, producing little resistance to its invasion of other parts.

Kruckmann reported years in sanatoria and clinics where active pulmonary cases were treated without observing a single ocular case; in eye clinics where ocular tuberculosis was relatively frequent, careful examination usually showed a tuberculous focus elsewhere, such usually being entirely quiescent, healed or calcified hilus glands.

Reviewing the literature on the subject the author finds reported out of approximately 20,000 cases of active pulmonary tuberculosis only about twenty-four cases of ocular tuberculosis, while careful examination of about 383 patients seen because of ocular tuberculosis, 208 revealed very slight changes on X-ray examination and fifty cases showed associated clinical findings, the majority of a very minor nature.

The author reports two cases occurring in young women with active pulmonary tuberculosis, in each case an iridochoroiditis which cleared up leaving a localized chorioretinal scar, very slight vitreous haze, and a complete restoration of vision. These two cases were the only ones seen in six years in an institution of 100 to 120 tuberculous inmates.

He concludes that tuberculous eye lesions are exceedingly uncommon in patients with phthisis and that while ocular tuberculosis is probably hematogenous and secondary to a focus elsewhere in the body, most often the tracheobronchial or hilus glands, the primary lesion is almost always slight, quiescent, healed or calcified.

M. F. Fellows, M.D.

INJURIES OF THE EAR FROM FRACTURE OF THE SKULL: E. D. Davis, London (Jour. of Laryng. and Otol., Vol. XLVI, No. 8, August, 1931). The author emphasizes the importance of immediate aural examination in cases of skull fracture, many of which involve the ear mechanism.

Cases involving the labyrinth are almost invariably fatal. Those involving the middle ear or external canal frequently recover. Hemorrhage from the canal is an unfavorable sign. If from both sides, the mortality is 66 per cent. Bleeding on one side alone shows a 39 per cent mortality. Some cases show hemorrhage into the middle ear without rupture of the drum membrane, which then appears bluish. Prolonged or copious bleeding from the canal means injury to the lateral sinus or middle meningeal artery and demands prompt surgical intervention.

Ear canals must not be plugged. Irrigation and "drops" are absolutely forbidden. If suppuration of the ear pre-existed, or develops later, the prognosis is much more unfavorable. Free drainage must then be provided at all costs (paracentesis), mastoidectomy if indicated. Recovered cases rarely suffer much hearing loss; when this does occur, it is of the middle ear (obstructive type). Immediate loss of hearing is common, but usually returns in three or four weeks. Seventh nerve paralysis is common but almost always recovers in weeks or months. Facial tics may be permanent. Tinnitis and dizziness may also be more or less troublesome over long periods.

Treatment means long periods of absolute rest in bed. No packing, no irrigation. Immediate establishment of free drainage should suppuration intervene, as only by this means can meningitis be forestalled.

M. W. Wheeler, M.D.

ENDOGENOUS PANOPTHALMITIS ACCOMPANYING TONSILLITIS: F. Flandreau Van Fleet, M.D., New York (Arch. of Ophthal., Vol. 6, September, 1931, No. 3). A short review of the literature indicates that the most common causative factor is puerperal sepsis although cases have been reported accompanying cholecystitis, prostatitis, pneumonia, measles, mumps, articular tuberculosis and influenza. No case has been reported due to metastasis from the tonsils. Bacteriologically the most common etiologic factors are the staphylococcus, streptococcus, pneumococcus and meningococcus.

The author then reports a case of a child, aged two, who had been suffering from tonsillitis for three days. On the second day she had pain in her right eye. The lids were edematous and tense; the cornea was hazy; the pupil was contracted and the conjunctiva was inflamed, although there was not much discharge. The general and local condition became much worse under routine treatment. Examination of the nose failed to show any involvement of the sinuses. X-ray of the sinuses showed moderate ethmoid involvement, especially on the left. Evisceration was done two days later, after which the patient made an uneventful recovery.

Culture from the conjunctival sac showed a profuse growth of Staphylococcus albus and short-chain nonhemolytic Streptococcus mitis. Culture from the tonsils showed a profuse growth of Staphylococcus albus and short-chain hemolytic Streptococcus pyogenes. At the time of operation, culture from the interior of the globe showed the same bacteriology as the tonsils.

Lucian G. Culver, M.D.

THE EFFECT OF TONSILLECTOMY IN ALLERGIC CONDITIONS: S. S. Bullen, Rochester, N. Y. (Jour. Allergy, July, 1931, Vol. 2, No. 5, p. 310). A study was made of the records of 600 patients with symptoms of allergic conditions in the upper or lower respiratory tracts. These cases had been followed for at least one year and many for ten years by personal observation or letter.

Patients with obvious gross infections such as chronic sinusitis, chronic bronchitis, bronchiectasis, etc., are excluded. On 300 patients tonsillectomies had been done—the remaining 300 served as controls. Seventy-nine and six-tenths had positive skin reactions by the scratch test. The treatment consisted in the removal of offending substances from contact with the patient whenever possible, as in the case of foods to which they were hypersensitive, animal emanations as in feather pillows, and so forth. Patients reacting to pollens were treated with pollen extracts.

The results of treatment are tabulated as follows:

OPERATED GROUP—PER CENT

Good	Fair	Poor	Failure
32.6	33.4	12.4	15.6
66			(6 refused treatment)

UNOPERATED GROUP—PER CENT

Good	Fair	Poor	Failure
31.7	37.7	12.0	16.6
69.4			(2 refused treatment)

The incidence of allergic manifestations in a ten year follow-up group of 2,000 children (Dr. Albert D. Kaiser's records) was as follows:

1,000 children (tonsillectomy)	1,000 children (controls)
41	Allergic coryza or asthma

Lawrence R. Boies, M.D.

THE SYMPTOM OF VERTIGO: W. E. Grove, Milwaukee (Arch. of Otolaryngology, August, 1931, Vol. 14, No. 2, p. 177). Turning vertigo is nearly always a sign of disturbed vestibular function; tactile vertigo may also at times be of vestibular origin. From an examination of approximately 300 patients suffering from injuries to the head, the author states positively that true turning vertigo accompanied by spontaneous nystagmus is present in a fairly considerable number of cases in which the most thorough and exacting examination of the peripheral vascular system revealed it to be functioning in a normal manner. It is the author's contention that in these persons the vertigo is caused by damage to the central vestibular area situated beneath the floor of the fourth ventricle.

If the patient exhibits true turning vertigo he must have or must at some time have had spontaneous vestibular nystagmus. This may not be present on every examination. It may be elicited by the head movement tests of Brunner.

The vertigo of a labyrinthitis or due to exclusion of a labyrinth by transverse fracture of a pyramid is violent and continuous. It improves after a few days and disappears entirely after a lapse of 5 or 6 weeks, because after this length of time the other labyrinth has learned to compensate for the loss of its mate.

The vertigo of a vasomotor disturbance in the central vestibular area is not continuous, nor is it so severe as to be completely disabling. It comes on in short spells of a few minutes duration brought on by such factors as rolling and turning in bed, looking up suddenly, bending the head forward suddenly, going above ground level, undue exposure to sunlight, mental and physical exertion, and even the slightest use of alcohol in any form.

The duration of the vertigo may assist one to some extent in making a diagnosis. In general, it may be said that if the vertigo lasts only a short time and then vanishes completely, it is more probably being caused by some acute condition of the labyrinth or vestibular nerve than a lesion in the brain stem. On the other hand, if the vertigo lasts longer and comes on in attacks over a period of years, it is more apt to be due to some lesion of the central nervous system although a chronic disease of the labyrinth cannot be excluded.

Lawrence R. Boies, M.D.

THE PATHOGENESIS OF OTOSCLEROSIS: K. Wittmaack, Hamburg, Germany (Arch. of Otolaryngology, August, 1931, Vol. 14, No. 2, p. 186). Wittmaack outlines the basis for his contention that venous stasis is an etiological agent in the production of otosclerosis. His investigations are in part supported by the Research Fund of the American Otological Society.

The author points out the generally accepted fact that the bony labyrinth normally differs from all other bones of the skeleton. It is formed on a cartilaginous capsule by endochondral ossification which starts from so-called points of ossification, in contradistinction to other endochondral bones. The labyrinthine capsule attains its final structure and size early in life and normally does not undergo further transformation. Consequently, the distribution of blood vessels, which is determined by points of ossification, also remains practically unchanged. These structural peculiarities are also found in some other mammals than man, and in certain non-mammals. In animals, however, spontaneous disease of the labyrinthine capsule similar to otosclerosis has not yet been observed. The author has, however, been able to reproduce repeatedly lesions in the hen which are essentially identical with the pathological processes seen microscopically in human otosclerosis.

The experimental production of venous stasis is accomplished by introducing ferric chloride into the intracranial median sinus. In 80 per cent of the cases positive results were obtained. Photomicrographs are reproduced comparing the experimental picture in the hen with the picture of human otosclerosis. The similarity is striking.

Lawrence R. Boies, M.D.

MEDICINE

TUBERCULOSIS ABSTRACTS*

As the mariner trims his sails to the weather, so the physician adjusts his therapeutic measures according to the pathological course of the disease. While general principles must guide us in the treatment of tuberculosis, no formula applicable to every case can be devised. If one understands the sequence of events following infection by bacillus tuberculosis, the response of the tissues and the natural processes of healing, treatment becomes more rational and adaptable to the immediate need. The most we can do in our present state of knowledge is to support the natural tendencies of the body to overcome the disease. M. Jaquerod of Leysin, Switzerland, discusses the natural processes of healing in pulmonary tuberculosis in *Tubercle,* of July, 1931. Abstracts of the article follow.

---

*Reprinted from Tuberculosis Abstracts, a review for physicians issued monthly by the National Tuberculosis Association, November, 1931, Vol. IV, Number 11.

Healing Processes in Tuberculosis

Radiography enables us to demonstrate the anatomical changes taking place in tuberculosis during life and ending in cure with a precision which is almost equivalent to post-mortem findings. Pulmonary tuberculosis was formerly considered as a chronic ailment from the very beginning. We now know that the disease passes through various stages before it arrives at a condition of chronicity. Virchow taught that all pulmonary tuberculosis lesions necessarily originated from miliary tubercles, solitary or conglomerate, and that these were the only specific lesions produced by the tubercle bacillus. Congestive or simple inflammatory changes in the region of chronic foci had been observed, but these changes were regarded merely as neighboring reactions without clinical significance. Today, we know that these lesions *are* tuberculosis, that they preceded the chronic lesions, and that during a period of a year or more they may exist alone and constitute the whole of the disease.

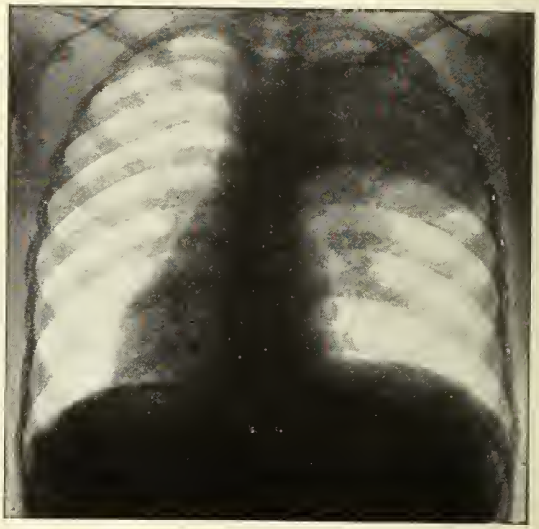
INFLAMMATORY NATURE OF TUBERCULOSIS

Wilson-Fox and Green, two English pathologists, recognized the pneumonic nature of the lesions (in 1873-74) before the tubercle bacillus had been discovered. Thaon, in France (1885), found that the tubercle bacillus was really the sole cause of tuberculous pneumonic lesions. Only ten years ago, the distinction between miliary (productive) and inflammatory (exudative) lesions was recognized in Germany.

This conception of the pneumonic or inflammatory nature of tuberculous lesions at their origin is of practical importance. As long as the lesions are in the inflammatory stage, they may heal by resolution comparable in every way to the resolution of the lesions in acute pneumonia, except that the process of regression lasts several months instead of one or two weeks. In the pneumonic stage, the bacilli are not yet solidly implanted in the tissues as in miliary type lesions but are still on the surface of the mucous membrane between the epithelial cells in the alveoli and the intercellular spaces. Consequently, their destruction and elimination by phagocytes or other means is rendered much easier. Only when these lesions do not heal do the manifold lesions of chronic tuberculosis develop, and these heal with greater difficulty. Indeed, when that has occurred, healing is possible only by the complicated processes of fibrosis and pulmonary retraction.

TIME ELEMENT IMPORTANT

The question, "How recent is the disease?" (that is to say, the lesion) has acquired a high clinical importance from the standpoint of prognosis and treatment. In recent pulmonary lesions, two types must be distinguished. The first type is encountered chiefly in childhood in an individual not previously infected and, therefore, non-allergic. If in this case the infection is slight, tuberculin sensitiveness will be produced but no actual disease capable of giving rise to clinical symptoms of obvious anatomical lesions. This the author calls abortive tuberculosis. But if the infection is more serious, actual disease may occur. The lesion is of relatively slight importance and it consists usually of an infiltration in the neighborhood of the point of inoculation with swelling of the lymph nodes at the hilum. These lesions are recognized by radiography. (In the United States, this type is designated as the childhood type of tuberculosis.) They regress slowly and heal by resolution, leaving no trace other than calcification in the hilum glands (tracheobronchial nodes). When the infection is too massive or if the resistance is not sufficiently good, the disease may continue to develop past the non-allergic phase and the lesions may soften or generalize.



X-ray plate, chest of boy, aged 8. Consolidation of right upper lobe with marked enlargement of lymph nodes from fourth to eighth posterior ribs. Physical signs: left, normal; right, limited expansion, dullness, bronchial breathing, and rales. Tuberculin test positive. Temperature up to 100.4° during dispensary observation. Twelve per cent underweight. Cough marked, sputum positive in April to animal inoculation; in May, to routine examination.

Twenty months later, the upper lobe had contracted somewhat and was less opaque; fresh infiltration had appeared in the middle lobe; the lymph nodes had diminished slightly and were beginning to calcify. In ten months more, both the upper and middle lobes cleared considerably and the outlook is now hopeful.

(From "Childhood Type of Tuberculosis," Chadwick and McPhedran, Nat. Tuberc. Assn.)

When bacillary infection takes place in an individual already sensitized by tubercle bacilli (reinfection), the pulmonary reactions may be much more intense, while the reaction of the pulmonary lymph nodes is almost nil. (In the United States, this form is called adult type of tuberculosis.) The inflammatory reaction may go so far as necrosis of parts of the lung, ending in cavity formation. But this cavity is quite different from that of chronic tuberculosis. Its walls are not formed by a well organized pyogenic membrane but by simple inflammatory tissue; and for that reason may heal by resolution without leaving any apparent fibrous scar. The cavity is, therefore, not always the final and most serious lesion of pulmonary tuberculosis.

The early forms of tuberculosis described are capable of cure by resolution; the chronic form only by the complicated processes of fibrous transformation and natural or artificial organic modification.

PNEUMOTHORAX FAVORED

The author is of the opinion that pneumothorax treatment is indicated in almost all cases of pulmonary tuberculosis as soon as diagnosed. Others consider that they are justified in waiting a certain time while placing the patient in the best possible condition for the cicatrization of his lesions. In favor of intervention, the author mentions the physician's preference for a method which enables him to play an active part and at the same time to verify speedily the results of his intervention.

He also feels that, as the first two or early forms always exist before the third, it is in these early stages that the bacillus can be most easily attacked, and, therefore, the possibilities of finding a remedy, of checking and curing pulmonary tuberculosis, are most promising if directed to the early types. He thinks, therefore, that the search for a cure should be directed to some remedy capable of facilitating the process of resolution. —*The Natural Processes of Healing in Pulmonary Tuberculosis, M. Jaquerod, Tubercle, July, 1931.*

THERAPEUTIC RESEARCH

The ideal of therapy is, of course, a practicable bactericide. Meanwhile, as we await this, it would appear that a study of structure would suggest the following paths as worthy of exploration:

1. That directed toward the discovery of a medium or method to accelerate and heighten cellular proliferation and fibrosis. Dangers lie in enhancing the tendency of tissues to tumor-formation.
2. That toward a medium to neutralize the intoxicating products of the allergic reaction. If it were non-specific, it might prove a veritable boon in many infectious diseases.
3. That toward a medium to neutralize the poisonous products that proceed from tuberculous foci. For reasons frequently expressed, it is believed that these are not specific, but are substances that result from the death and disintegration of the cellular components of foci. Can a substance antagonistic to them be found? Or a substance that would so act upon the body as to ward off their physiological effects?—*The Evolution of Tubercle, Allen K. Krause.*

LEUKOCYTIC REACTION IN TUBERCULOSIS OF INFANTS AND CHILDREN: Carl H. Smith (Amer. Jour. of Med. Sci., August, 1931).

The important white blood count is best demonstrated by the newer technic. It reflects the pathological status of the tuberculous lesion.

Sabin comments as follows: The major effect of tuberculosis is on the monocyte. The bacillus grows within the monocyte. The lymphocyte is concerned with limitation of the spread. This reaction may be measured by the preponderance of the lymphocyte. The activity is indicated by increased monocytic count. Reversal of the normal relationship indicates activity or extension. When arrest takes place, lymphocytes are increased. Medlar emphasizes the fact that the polymorph-neutrophile indicates tuberculous abscess formation. The supra-vital technic of Sabin allows of examination of cells in the living state, thus allowing more accurate cell differentiation.

STUDY

The monocyte (identical with the transitional cell of Ehrlich, including also what is known as the large monocyte) has an eccentric nucleus and is distinguished by a rosette about the centrosphere. The monocyte loses its motility when it becomes the host of the bacillus, and is stimulated or modified. Result: development of the epitheloid and later the giant cell of Langhans. These changes may be seen in supra-vital films.

The study included 291 supra-vital counts. Ninety-three cases were infants and children. Fifty were of the normal group. (*See* tabulated results.) The results would indicate, (1) that increase of the neutrophiles and monocytes is related in an important way to extension and activity; (2) that lymphocyte increase is associated with resistance; (3) that normal children have a high lymphocyte count—lymphocyte comparisons must be made with the normal; (4) that the monocyte-lymphocyte ratio increases with age from .09 to 1. In acute tuberculosis there were seventeen cases; fourteen of these were meningitis from five to six years.

RESULTS

(1) The total white blood count was elevated.

(2) Neutrophilic leukocytes and monocytes were increased.

(3) Lymphocytes were decreased.

(4) Stimulated or modified monocytes were frequent.

Epitheloid cells were less frequent. In the sub-acute and chronic form there were ten cases. Three patients had pleurisy, two epituberculosis. Five had extra-pulmonary forms. These, especially the extra pulmonary forms, had low monocyte-leukocyte ratios.

In latent forms of tuberculosis with a positive reaction to low tuberculin dilutions, eosinophiles were above normal in one-half the cases.

Rich remarks that allergy and resistance cannot be used interchangeably.

Sabin notes that the monocytes and their derivatives are hosts of the tubercle bacillus and are related to dissemination. Epitheloid cells are found in Hodgkin's disease. Regression and progression are reflected in the peripheral blood picture.

CONCLUSIONS

(1) The blood picture of a tuberculous infant may be co-related with the activity of the pathologic lesion.

(2) The complete index of activity is as follows:
    (a) Increase in white cell count.
    (b) Elevation in p.m.n. and monocytes.
    (c) Drop in eosinophiles and lymphocytes.
    (d) Rising monocyte-leukocyte ratio.
    (e) Reversion to former type in healing.

(3) The trend is ascertained by numerical comparison, emphasis on the monocyte-leukocyte ratio.

(4) This examination often furnishes the earlier signs of change in the status of the disease in childhood.

J. G. Lamont, M.D.

URINARY ACIDITY IN TUBERCULOSIS: K. L. McCluskey, Chicago Municipal San. (Amer. Rev. of Tuberc., August, 1931, XXIV, p. 182). *Pathological conditions* resulting in acidosis are: Diabetes mellitus, uremia, nephritis, rheumatism and heart diseases.

Normal metabolism produces acids which are removed by the lungs (carbonic acid), kidneys (mineral and organic acids), and skin. Excessive tissue destruction and metabolism of the tubercle bacillus itself throw greater demand upon the governors or regulators of body-neutrality. Disturbances may be expected to appear first in the urinary secretion.

Acidosis results from *over-production* or *retention* of acids. Acid waste is neutralized by blood alkalies. The kidney returns part of the alkali to the blood and excretes the rest as salts. If the acid products are not neutralized by blood alkalies, the urinary picture is that of decreased pH, increased titratable acidity and decreased normal dibasic phosphate and ammonia. The kidney is thus called upon to excrete a urine of higher acid intensity. The result is frequent, slight albuminuria. In acidosis, with neutralization by blood alkalies, there is lack of alkali conservation. The urine shows increased pH and a lower titratable acidity with an increase of dibasic phosphate.

The study included eighteen subjects:

Group I—6 patients working 3 to 5 hours daily.
Group II—3 patients, confined to bed.
Group III—6 patients, critically ill.
Group IV—3 normal subjects.

All of the urines were free from sugar and albumin, except two minor albuminurics who were critically ill.

Urine was collected for a day-period and a night-period, 8 to 8, and these were analyzed separately, for: (1) ammonia, (2) titratable-acidity, (3) pH, (4) creatin, (5) creatinin, (6) organic acids.

CONCLUSIONS

1. The pH value of the first two groups was identical with the normal group for the day-period.
2. The pH value of the night-period for group I is below that of normal group, and group II is still lower.
3. The creatinin co-efficient is lowered with the severity of the disease. There is greater creatinin secretion at night.
4. Creatinin values are variable.
5. Critically ill patients had an increase in ammonia; conclusion, overwithdrawal of fixed alkalies.
6. The amount of titratable acidity is greater at night than at day.
7. Total inorganic acids fall consistently from group I through group III.
8. Total organic acids are lower than normal except the critically ill, who show an increase over group II.
9. The quantity of inorganic acid slightly exceeds the organic acid.
10. Tuberculosis causes a mild but not a pronounced degree of acidosis. Blood alkali is conserved first and later depleted in the advanced stages.
11. A pre-eminently base-forming diet would assist the body in overcoming the acidosis.

John G. Lamont, M.D.

PEDIATRICS

STUDIES IN SCARLET FEVER VI—COMBINED ACTIVE AND PASSIVE IMMUNIZATION TO SCARLET FEVER: A. Lichtenstein (Acta Paediatr. X:4:539, June, 1931). From the Epidemic Hospital at Stockholm, Lichtenstein reports the results of attempts to secure immunity to Scarlet Fever by a combined method of serum and vaccine treatment. The 82 persons chosen for the experiment had all been directly exposed to the disease and showed positive Dick reactions. The adults were given either 20 c.c. of scarlatinal streptococcic serum or 50 c.c. of convalescent's serum—children, one-half the dose. Immediately, and within a week's time, each was also vaccinated with toxin plus bacteria. The vaccine was injected at intervals of three to seven days for five doses, adults receiving respectively 100 million, 500 million, 1 billion, 2 billion and 5 billion streptococci and 30, 150, 300, 600 and 1,500 skin test doses. Children under five years were given 100, 300, 500 and 700 million and 1 billion streptococci respectively, combined with 30, 90, 150, 210 and 300 skin test doses. The patients experienced no discomfort subsequently. In twenty-seven of forty adults and in thirty-seven of forty-two children, the Dick test turned to negative following the serum injection. All were found Dick-negative after vaccination. In none of the three groups thus treated was there any further scarlet fever for the next few months. One of the children contracted the disease five months later, and, upon testing, six out of twenty children were found to have positive Dick reactions at the end of six months, though weaker than previously.

The author is conservative in drawing his conclusions, but believes that the results are encouraging enough for further investigation, and suggests that increased doses of vaccine might prolong the period of immunity.

L. G. Frary, M.D.

STUDIES IN SCARLET FEVER. VII: TREATMENT WITH STREPTOCOCCUS ANTITOXIC SERUM: A. Lichtenstein (Acta Paediatr. X:5:549-575, June, 1931). Scarlatinal streptococcus antitoxic serum was first used at the Epidemic Hospital of Stockholm in 1925, and the author was so impressed with its value that it has been used in all serious cases since that time, unless there was some contra-indication. He now reports data from the years 1926-1929 inclusive, during which time, 2,104 cases of scarlet fever were admitted, of which 512 were given antitoxic serum.

He regrets the lack of a control group but did not feel justified in choosing only alternate cases because of the efficacy of the treatment. Children were given an intravenous dose of 10 c.c. immediately; adults, 10 or 20 c.c., depending on the severity of symptoms. The dose was repeated on the next day if there was no definite result, unless complication developed. In a small group, serum was injected intramuscularly.

It was early discovered that results were entirely different in complicated and uncomplicated cases. Where there was no complication, there was regularly noted a critical fall of temperature immediately after the injection, to about 37° C., with a corresponding rapid improvement of all symptoms. In 280 out of 350 patients, the result was of this type, *i.e.,* "complete"; in fifty-seven, there was a critical fall to about 38° C. and a decided improvement, *i.e.,* "good"; in thirteen, results were negative. In a series treated with convalescent serum, results were less favorable, 219 being "complete," ninety-two "good" and thirty-nine negative. For reasons given later, serum should be given early, although it was found to be effective as long as toxic symptoms were present, even into the second week.

Serum treatment was ineffective against already existing complications—in fact the author believes that failure to secure an immediate complete serum effect is evidence of presence of a complication, and should indicate a thorough search for such a complication. Improvement in the general toxic condition of the patient even in the face of complication, however, seems to occur, so that he favors giving serum. Early serum treatment may reduce the frequency of complications, but, after the third day, such is probably not the case. There were no deaths in cases treated before the onset of complications, nor among those which were so mild from the start that serum was not considered necessary. In three of the eight deaths occurring in the series given sera, scarlet fever was only a contributory cause of death; in the other five, the powerlessness of sera against existing complications was clearly demonstrated.

There was little serum sickness, and few bad effects resulted from treatment, all of which were easily controlled. The author suggests that the unfavorable effects reported in America may be due to the use of a more concentrated serum than that made in Sweden. Throughout this study, Swedish serum was used. As to effect on mortality, the author prefers to draw no definite conclusions, since there has been a general decrease in the severity of the disease in Sweden, and since he had no control group. He believes the real test will come when a severe epidemic occurs.

L. G. Frary, M.D.

VIOSTEROL AND COD LIVER OIL! E. O. Prather, Jr., M.S., Instructor in Pharmacology, University of Tennessee; Martha Nelson, M.S., Asst. in Research, Edward Clay Michell Clinic; and A. Richard Bliss, Jr., M.D., Chief, Division of Pharmacology, Memphis, Tenn. (Amer. Jour. of Diseases of Children, July, 1931, Volume 42, Number 1).

Because of the vagueness and the indirectness of some manufacturers' statements concerning viosterol, there is a growing belief among pediatricians and physicians in general that viosterol is a concentrated substitute for cod liver oil, and the substance is enjoying an increasing popularity as a "substitute for cod liver oil."

Although aware of the fact that cod liver oil contains two vitamins and viosterol only one, the average physician is better acquainted with the antirachitic vitamin, and is likely to disregard the importance of fat-soluble vitamin A and its influence on the child's resistance to infections.

When animals are fed a purified diet adequate in proteins, inorganic salts, calorics and vitamin B, they grow well for a short time; then the weight becomes stationary or decreases rapidly, and xerophthalmia develops. The upper respiratory tract becomes inflamed; the liver and spleen become discolored, shrunken and infiltrated with fat; the kidneys become sand-colored, and the intestines are found to be thin-walled and filled with gas. In some cases, the stomach, as well as the entire intestinal tract, is badly distended. No visible intraperitoneal fat is present. The intestines vary in color from dull brown to a degree of inflammation that is almost red. The amount of calcium deposited in the bones is very small.

The addition of viosterol to a diet like the aforementioned one increases the calcification of the bones, but it does not prevent or cure the xerophthalmia or increase the growth of the animal. The addition of cod liver oil to the aforementioned diet results in excellent growth of the animals, a better calcification of the bones, an increased deposition of body fat and normal respiratory tracts, and the liver, kidneys, spleen and intestines are found to be normal.

Viosterol, therefore, does not demonstrate the power to stimulate growth and development of the body and vital organs, or to prevent infections of the upper respiratory tract or to produce the same degree of calcification and growth of the bones as does cod liver oil.

Since "colds," malnutrition and intestinal inadequacies are more frequent in children than rickets, this study emphatically suggests that the apparently widespread substitution of viosterol for cod liver oil in the diet of the child is not logical and may result in an appreciable decrease of the child's strength and resistance to infections.

R. N. Andrews, M.D.

HIRSCHSPRUNG'S DISEASE TREATED BY LUMBAR SYMPATHECTOMY: T. Wood Clarke, M.D., and Frederick M. Miller, M.D., F.A.C.S., Utica, N. Y. (Arch. of Ped., September, 1931, Vol. XLVIII, No. 9). Congenital idiopathic dilatation of the colon, megacolon, giant colon, or Hirschsprung's disease, is a congenital malformation characterized by dilatation of the colon, abdominal distention, obstipation, at times alternating with diarrhea, emaciation, and general weakness.

The surgical treatment, until recently, has consisted of colostomy with artificial anus, or of colectomy. The most recent surgical suggestion is lumbar sympathectomy.

In 1924, N. D. Royle, the orthopedic surgeon, and John I. Hunter, Professor of Anatomy of Sydney, Australia, working together, proved experimentally that resection of the sympathetic ganglia relieved the spasticity of the extremities in animals in which artificial spastic paralysis had been produced. Hunter further showed that in paralyzed animals in which the distal portion of the colon was quiescent and dilated, excision of the lumbar ganglia caused immediate resumption of activity of the distal colon and expulsion of feces.

In 1929 and 1930, Learmouth and Markowitz of the Mayo Clinic, by animal experimentation, confirmed the researches of Langley and Anderson, and of Hunter. Among their conclusions are that section of the lumbar colonic nerve invariably leads to an immediate increase in intracolonic pressure and in the amplitude of the contraction of the colon, and that the internal sphincter derives a certain amount of motor innervation through the lumbar sympathetic outflow.

Merle, Scott and Morton add a contribution by demonstrating in two cases of Hirschsprung's disease that spinal anesthesia temporarily terminated the motor inertia of the large bowel and caused copious bowel movements.

The results of the operation of lumbar sympathectomy, in the small number of cases in which it has been performed, have been uniformly favorable. The patients have shown remarkable improvement in their general health. The abdominal distention has decreased with variable rapidity, and the patients, who previously had suffered from obstipation, report regular bowel movements once or twice a day, usually without the aid of laxatives or enemata. There have been no deaths reported from the operation. No untoward symptoms in reference to other pelvic organs have occurred.

R. N. Andrews, M.D.

FEBRIPHOBIA: Charles Herrman, M.D., New York (Archives of Ped., September, 1931, Vol. XLVIII, No. 9). There are three manifestations in children which cause great anxiety to the parents and often take the physician out of his comfortable bed at night—convulsions, severe hemorrhages and high temperatures. The significance of high temperature depends on its cause. In some cases it may represent a favorable reaction. The febrile reaction seems to represent an attempt on the part of the organism to counteract the injurious effect of the entrance of foreign material, an increased effort to fight the disease by stimulating the circulatory, respiratory and endocrine systems. As is well known, the good effect of baths, douches and packs is not due solely to the reduction of temperature, for this is often slight, but also to the favorable effect on the nervous system.

The fact that a given procedure results in a reduction of the temperature is not in itself proof that the patient is benefited and the disease controlled. Antipyretic drugs, aside from their depressing effect on the heart, may interfere with the rapid development of antibodies.

Apparently a high temperature, like a high polymorphonuclear leukocyte count, indicates a severe infection, but such patients may also have a good resistance. It is important to know whether, in addition to the high temperature, the patient presents other serious manifestations, such as a poor circulation and disturbances of the nervous system. If the child has an appetite and requests food there is no reason why at least carbohydrates and fruit juices should not be given. Fluids in sufficient quantity are absolutely essential and should be insisted on to prevent dehydration, to increase elimination and the removal of ketone bodies.

The anxiety produced by a marked rise in temperature in children, when unaccompanied by other serious manifestations, is out of all proportion to the danger.

R. N. Andrews, M.D.

ABDOMINAL PAIN IN CHILDREN WITH UPPER RESPIRATORY INFECTIONS: Ralph R. Scobey, M.D., Syracuse, N. Y. (Arch. of Ped., September, 1931, Vol. XLVIII, No. 9). Abdominal pain in children, resulting from infections of the upper respiratory tract, occurs more frequently than is generally supposed.

Brennemann, in 1921, and again in 1927, called attention to the incidence of this condition in connection with throat infections. The pain was usually in the region of the umbilicus. Brennemann felt that the cause of the abdominal pain was due to mesenteric or retroperitoneal lymphadenitis. His conclusions were prompted by the fact that it was usually present during the acute infection and often outlasted it. Enlarged abdominal lymph nodes were often observed in cases of this kind, which were operated. He also called attention to similar adenopathy found at autopsy in cases of influenza.

The fact must always be borne in mind that a pathological appendix can co-exist, or be secondary to an upper respiratory infection. Attention has been called by many writers to the fact that cases of appendicitis may occur in greatly increased numbers during epidemics of grippal infections.

Another condition, which has received little attention in the literature as a cause of abdominal pain, is "irritable colon." MacDonald calls attention to this condition associated with acute upper respiratory infections. There is still another condition which is responsible for abdominal pain and which may manifest itself during an acute upper respiratory infection, namely, pyelitis.

While it has been shown that abdominal pain may result from infections of the upper respiratory tract, one must not lose sight of the fact that serious abdominal pathology may exist and be entirely independent. It must be remembered, also, that appendicitis is one of the commonest causes of abdominal pain and may present itself much more frequently during epidemics of upper respiratory infections.

ROENTGENOLOGY

OBSTRUCTIVE LESIONS OF THE SMALL BOWEL: C. H. Heacock (*Radiology,* July, 1931, XVII, 119-124). Cases of intestinal obstruction fall into one of the following groups: (1) Those in which a clear-cut, definite clinical diagnosis can be made and in which the findings localize the site of the obstruction, (2) those in which the clinical diagnosis is definite but in which there are no localizing symptoms or findings, (3) those in which the diagnosis is uncertain, and (4) those in which the diagnosis is not even suspected by the clinician.

Whenever there is any doubt about the presence or location of an obstruction, *i.e.,* in the last three groups, there is an indication for a roentgenologic examination. The extent of the examination and the amount of work required will depend largely upon how acute and how complete is the obstruction.

If the roentgen examination is to be of much benefit in the acute cases, it is of utmost importance that the examination be completed quickly and with minimal tax upon the strength of the patient. These acute obstructions usually develop soon after an operation. It is important to make this examination in both the supine and erect positions, and with the motor-driven table both fluoroscopic and radiographic studies can be made without any exertion on the part of the patient. If the patient cannot be removed from his bed, roentgenograms can be made in two planes without moving him and a great deal of information obtained.

While small amounts of gas may exist normally in the small bowel, the only collections of gas seen on the radiographs of normal individuals occur in the stomach and colon. Collections of gas in the small bowel are, therefore, always significant, and, when the additional signs of distention and fluid levels are present, definite criteria for the diagnosis of obstruction may be said to exist. The fluid may be easily overlooked unless the patient is examined in two planes, preferably the supine and the erect postures.

Usually the appearance and distribution of the gas enable the roentgenologist to determine its location. In the small bowel haustral markings are absent, while the valvulæ conniventes stand out prominently.

In chronic or partial obstruction there may be no distended loops of small bowel and no information obtained on what Davis calls the "scout film." In this type of case the administration of barium is necessary to make the diagnosis. It is also in this type of case that the diagnosis is most often doubtful and the need for immediate interference not so urgent. Within this group fall the neoplasms—both benign and malignant—and it must be remembered that the early detection and localization of the latter lesions determine the success of the treatment. The examination with the ingested meal, which may require forty-eight hours, is permissible. Thus far no untoward effects have been observed.

There are two reliable roentgen signs of partial obstruction. One is dilatation of the lumen proximal to the obstruction and the other is a disturbance in motility. The slowing up and damming back of the current is manifest throughout the small intestine, and there may even be a gastric retention. The delay becomes progressively more pronounced until the point of obstruction is reached. After passing this point the normal progress of the meal is resumed. It is important for the roentgenologist to know the normal motility for the opaque mixture he is employing. This will vary somewhat, depending upon how much fat and carbohydrate are added to the barium. Delayed motility due to obstruction must not be confused with stasis in the small bowel without mechanical obstruction. Stasis usually occurs in the ileum and may be associated with no organic lesion. Lesions in the colon, especially the right half of the colon, must be ruled out and the possibility of a regurgitation through the ileocecal valve must be considered. The finding of barium at the twenty-four-hour observation is always significant and, in the absence of a lesion in the colon, generally means an obstructive lesion in the terminal ileum. While there is delayed motility in both stasis and obstruction in the former, dilatation of the lumen does not occur.

John D. Camp, M.D.

ELABORATION OF CRITERIA UPON WHICH THE EARLY DIAGNOSIS OF ACUTE INTESTINAL OBSTRUCTION MAY BE MADE. WITH SPECIAL CONSIDERATION OF THE VALUE OF X-RAY EVIDENCE: Owen H. Wangensteen. (*Radiology,* July, 1931, XVII, 44-62). The present high mortality in acute intestinal obstruction is due in large measure to late diagnosis. Revision of the usual criteria upon which the diagnosis of bowel obstruction is made is urgently indicated. Obstipation, regurgitant vomiting, and general abdominal distention portend the beginning of the end of life for the unfortunate sufferer with bowel obstruction. These must cease to be occurrences awaited before the diagnosis is made.

Intermittent, crampy, colicky pain associated with nausea and vomiting but unattended by local physical findings suggests acute intestinal obstruction. The bowel below the point of obstruction is physiologically as well as anatomically normal and will expel an administered enema, with the return of gas and feces. Gaseous shadows in the small intestine demonstrate the presence of intestinal stasis. The "ladder pattern" of gaseous distention in the small intestine need not be awaited to make the diagnosis. The stethoscope serves to distinguish whether the stasis is mechanical or paralytic in character. When the diagnosis is made early the mortality of operation for acute intestinal obstruction will exhibit a like improvement to that long ago manifest in the surgery of most other acute abdominal catastrophes.

In simple obstruction to the continuity of the small intestine gas may be visualized in the small intestine usually within four or five hours after the onset of symptoms. When the obstruction is in the colon a variable time may elapse before gaseous distention of the small intestine becomes visible on the X-ray film. In strangulation obstructions gaseous shadows in the small intestine do not appear as early as in simple obstructions and this criterion is, therefore, not as reliable an index as in the latter type of bowel occlusion. In vascular occlusions of the mesenteric vessels, gaseous distention does not occur as early as in simple obstruction. In the inhibitive ileus of peritonitis, gaseous distention of the small intestine may be observed early. Gaseous distention of both colon and small intestine is almost invariably present. The presence of dense "bands" between the dilated intestinal loops suggests the presence of exudate between the intestinal coils.

The entity of functional spastic ileus which simulates mechanical obstruction in all clinical features may be identified by proper correlation of clinical and roentgen findings. The special uses of X-ray evidence of obstruction are enumerated for intestinal atresia, imperforate anus, and intussusception. In the latter condition the barium enema may frequently be employed to reduce the invagination.

John D. Camp, M.D.

THE ROENTGEN DIAGNOSIS OF AORTIC ANEURYSM: Harper G. Sichler (*Radiology*, August, 1931, No. 2, 304-316). Comparative clinical and autopsy statistics indicate that many cases of aortic aneurysm are not diagnosed during life. Sacculated aneurysms, while the most common, are not the only type of aortic aneurysm, and the roentgen diagnosis should not be made contingent on finding local sacculations. All cases of syphilitic aortitis with dilatation should be kept under observation until it has been determined by the progress of the lesion whether or not the aortitis is complicated by aneurysm formation. Squaring of the aortic arch is characteristic of syphilitic aortitis.

A study of seventy-seven cases of aortic aneurysm occurring during a five-year period demonstrated the percentage of occurrence to be 0.06 per cent, that the proportion of syphilitics with aortic aneurysm was 1.6 per cent, and that of the total number of aneurysms 97 per cent were of syphilitic origin. The roentgen examination discovers a large number of cases of aortic aneurysm (nearly 30 per cent of this series) which produce no clinical signs or symptoms of their presence.

John D. Camp, M.D.

THE OSSEOUS CHANGES IN HYPERPARATHYROIDISM ASSOCIATED WITH PARATHYROID TUMOR: A Roentgenologic Study: John D. Camp and Harold C. Ochsner (*Radiology*, July, 1931, XVII, 63-69).

The roentgenographic changes observed in the osseous system in two cases of hyperparathyroidism associated with tumor of the parathyroid glands are presented. The osseous changes in roentgenograms consists of generalized osteoporosis, cystic lesions, and deformities. The generalized osteoporosis is characterized by a miliary or granular appearance. This change is best observed in the skull and appears to be peculiar to hyperparathyroidism. In addition, the bone trabeculæ and cortical bone are thinned, and areas of subperiosteal absorption are seen in the long bones and phalanges. Single or multiple cystic lesions are found in the jaw, pelvic bones, and long bones. These lesions are often confounded with those of osteitis fibrosa and with giant-cell tumor. The deformities due to softening of the bones consist of kyphosis, narrowing of the pelvis, coxa vara, bowing of the legs, and infractions. It is not unlikely that pathologic fractures may even occur. In addition, renal calculi are not uncommonly found. In each instance, removal of a parathyroid tumor was followed by a definite arrest of decalcification and progress toward restoration of normal bone structure, as observed roentgenographically.

John D. Camp, M.D.

SURGERY

TREATMENT OF VARIOUS PERIPHERAL PAIN SYNDROMES BY SUBARACHNOID ALCOHOLIZATION OF POSTERIOR NERVE ROOTS, AT THEIR EMERGENCE FROM THE SPINAL CORD: A. M. Dogliotti, M.D., University of Turin, Italy, La Presse Medicale, Number 67, August 22, 1931.

The author reviews the various nerve tracts by which pain is carried from the periphery to the brain. In such conditions where the usual conservative treatment does not help, before resorting to the more serious surgical attacks, such as laminectomy, postero-radicotomy, and anterior lateral cordotomy (procedures which, besides being serious undertakings, are not always reliable for physical and anatomical reasons), he proposed, and has used, subarachnoid injections of absolute alcohol to block these nerves, and in this way relieve or cure painful conditions of various kinds. The substance used is absolute alcohol, which he has shown by in vitro laboratory test will rise to the surface of spinal fluid, and mix with it very slowly. Dosage and physiological effects have been studied in the dog, and later used in the human in a series of 45 cases.

The method consists in making the usual lumbar puncture at a pre-determined site in the median line between the spinous processes; for pain in the sacral plexus, the interval between the 5th lumbar and 1st sacral is used; for pain in the lumbar roots, the spaces between 3rd, 4th, and 5th lumbar are used; for the lateral femoral-cutaneous and ilio-inguinal regions, the injection is made between the 2nd and 4th lumbar vertebræ; for visceral abdominal and lower intercostal pains, the space between the 12th dorsal and 1st lumbar, or, better, between the 1st and 2nd lumbar vertebra, is used; for intercostal injection, the corresponding vertebral space is used; for pains in the upper extremities, the lower cervical spaces would be indicated were it not for the difficulty of the intervention of the cervical dorsal protrusion of the cord, so that, instead, the space between the 4th and 5th dorsal vertebræ is used, assisted by placing the patient in such elevation of the trunk as to locate the alcohol in the desired region of the cord.

The patient is put in the classical position for the spinal puncture, and then caused to lie down on that side which is opposite to the side of pain. The elevation of the pelvis or shoulders is modified from 10 to 30 degrees, depending upon the region which it is desired to treat, the lighter absolute alcohol flowing always to the top. A syringe which is graduated in 0.1 c.c., which is equivalent to the tuberculin syringe, is used. The injection is made very slowly, drop by drop, so as to avoid mixing the alcohol in the spinal fluid. Depending upon the gravity of the neuralgia, one injects from 0.2 to 0.8 c.c. of absolute alcohol. The patient at once has a sense of heat in the affected territory, followed in ten to fifteen minutes by a zone of hypersthesia and some points of total analgesia. The tendinous as well as cutaneous reflexes are lessened and often completely disappear, and there is a slight motor disturbance, which disappears completely in a few hours, occasionally within a few days.

The painful symptoms, however, disappear in ten to fifteen minutes. In order to prevent the fluid from affecting the motor roots, the patient, besides lying on his side, inclines somewhat into the prone position. The effect of the injection is to stop the pain or to lessen it, and cure is brought about either directly by cutting out the irritating peripheral stimuli, or by stepping down its transmission through areas in which pain sense is relayed to the brain.

The forty-five cases in which this method was used include: twenty-two cases of subacute sciatica, unrelieved by more conservative methods; nine cases of funiculitis with radicular symptoms, and osteo-articular alterations in the spinal column; three cases of neuralgia of the lateral cutaneous nerve; one case of intercostal neuralgia, due to herpes zoster; two cases of sacrococcygeal neuralgia; two cases of painful stump following amputation; two cases of tabetic girdle pains; and two cases of acute circumscribed pain, (1) the interior border of the foot, (2) of the testicle and anus.

There was amelioration or cure in most of these cases, with the observation that the more diffusely distributed the pain is the better the results are. It is wise, for this treatment, to have the patient in the clinic or hospital, where, if necessary, he can be kept under observation, sometimes in bed, for two or three days. The treatment can be repeated in ten to fifteen days, if the result is incomplete.

Besides the type of cases in which the author has used this treatment, such cases where radicotomy has been used would offer a suitable field for this treatment, such as cases with profound modification of muscular tone, as Little's disease or other painful contractures. The method proposed is considered superior to more peripheral treatment, such as paravertebral or peripheral injections; on the other hand, it is not as serious an undertaking as laminectomy, postero-radicotomy, or antero-lateral cordotomy.

Three illustrations accompany the article.

CONSULTATION BUREAU

(Continued from page 1006)

between them cannot be determined in advance. The usual practice is to give subcutaneous injections at five to seven day intervals. The exact time and number depend on the local and general reaction. The local reaction is the important guide to treatment. As a general rule, this is never allowed to exceed the size of a fifty-cent piece and the next dose is made larger or smaller on the basis of the previous reaction. Co-seasonal treatment of small repeated doses is sometimes used. Treatment may even be of benefit late in the season. General reactions may be serious and should be avoided if possible. Perennial treatment is based on the assumption that specific doses of the pollen about once a month would give better results. Whether one or more pollens should be used is a matter of judgment.

The results of desensitization are on the whole satisfactory. Whether permanent effects are obtained is still doubtful. In a total of 410 patients with ragweed hay fever who were treated and appeared to have relief of symptoms for at least two years without further treatment, in the meantime, 6.3% were cured; of the remainder, 238, or more than half, were greatly improved, 73 were improved, and 73 were the same. The spontaneous disappearance of hypersensitiveness is well known. How often it occurs is still very difficult to decide. This subject is very large and it is impossible to give you any more than a bare outline of some of the more important features.

SILVER NITRATE AMPULES AND CAPSULES

The A. M. A. Chemical Laboratory undertook an investigation of silver nitrate capsules and ampules to determine whether the market supply was satisfactory. The Laboratory found that the various brands of silver nitrate ampules contained in both wax and glass ampules showed that the strength of the silver nitrate solution is generally somewhat greater than the amount claimed and that practically none of the silver is absorbed by the wax ampule. The quantity of solution found in the glass ampules complied with that claimed. On the other hand, in the wax ampules not only did the quantity of solution vary with each brand, but the products of the various firms differed markedly, ranging from 0.07 c.c. to as high as 0.26 c.c. The Laboratory points to the possible danger from fragments of glass which may form when the glass ampule is opened and which may reach the infant's eye when the silver solution is instilled. The Council on Pharmacy and Chemistry considered the report of the Laboratory and authorized its publication. In recommending endorsement and publication of the report the Council's referee expressed gratification at the reassurance given by the report that the wax capsules do not inactivate the silver nitrate and called attention to the fact that the use of glass ampules may be an open invitation to accident. (Jour. A. M. A., September 5, 1931, p. 706.)

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

Bulletin of the National Research Council. Number 83. A compendium of the statute law of coroners and medical examiners in the United States. George H. Weinmann. 240 pages. Price, paper cover, $3.00. Washington, D. C.; National Research Council, 1931.

Simplified Diabetic Management. Joseph T. Beardwood, Jr., A.B., M.D., F.A.C.P., and Herbert T. Kelly, M.D., A.A.C.P., both from Diabetic Clinic of Presbyterian Hospital in Philadelphia, etc. 190 pages. Price, cloth, $1.50. Philadelphia: J. B. Lippincott Company, 1931.

Medical Jurisprudence. Alfred W. Herzog, Ph.B., A.M., M.D., Honorary Academician of the International Academy of Letters and Sciences, Editor of The Medico-Legal Journal. 1051 pages. Price, $15.00. Indianapolis: The Bobbs-Merrill Company, 1931.

Surgical Pathology of the Skin, Fascia, Muscles, Tendons, Blood and Lymph Vessels. Arthur E. Hertzler, M.D. Surgeon to the Agnes Hertzler Memorial Hospital, Halstead, Kansas, Professor of Surgery, University of Kansas. 301 pages. Price, $5.00. Philadelphia: J. B. Lippincott Company, 1931.

INTESTINAL TOXEMIA (AUTOINTOXICATION) BIOLOGICALLY CONSIDERED. Anthony Bassler, M.D., F.A.C.P. Illustrated with 16 text cuts, 433 pages with index, reference from Epistle of St. Paul, dedication—In Memoriam, preface by the author, contents, 4 charts inserted immediately following the index at the back of the book. Price: $6.00. Philadelphia; F. A. Davis Company, Publishers, 1930.

An incentive to research and a stimulus to painstaking, unrelenting study, the work embodies the treatment of 5,000 patients, seen during a period of 30 years of the author's own experience. The work involved constant research, examination, checking and rechecking, with estimations of immediate results and those apparent years after termination of treatment. The clinical side of the subject is handled with the clinical entity terms in specialty groupings used as headings.

The charts inserted in the pocket in the back cover of the book minutely consider: 1. Cultural Characteristics of the Intestinal Pathogenic Organisms. 2. Cultural Characteristics of the Intestinal Saprophytic Organisms. 3. Cultural Characteristics of the Intestinal Zymogenic Organisms. 4. Cultural Characteristics of the Intestinal Non-pathogenic Organisms.

As a reward for this expression of his life's work may the author's wish in the preface be fulfilled!

Lillian L. Nye, M.D.

WHAT THE PUBLIC SHOULD KNOW ABOUT CHILDBIRTH. Gossett. 290 pages, $2.00. The Midwest Co., Minneapolis, 1931.

There is nothing in this book about childbirth that the public should know. There is a great deal that the public may know. The welfare of the individual patient and the maternal mortality rate can be best served if the public follows a brief instruction that can be summarized in eight words. "Engage your physician early; follow his instructions faithfully."

There is a great deal in this book, however, that the physician should know and also that he may know.

A. G. Schulze, M.D.

WANTED—Salaried appointments for Class A Physicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nation-wide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan Ave., Chicago. Established 1896. Member The Chicago Association of Commerce.

FOR SALE—Office equipment including X-ray. Location in Minnesota town of 1,400 people. Average income of over $5,000 yearly for the past eight years. Unopposed. Specializing. Address D-150, care Minnesota Medicine.

GRADUATE of medical secretarial course, Rochester Junior College, Rochester, Minn., desires work. References. Address D-152, care Minnesota Medicine.

FOR SALE—Office equipment of the late Dr. O'Hara including leather upholstered Yale operating chair, instruments, drugs, bandages, also medical books. Can be seen by appointment. Telephone Mrs. Lola O'Hara, No. 67, Janesville, Minnesota.

FOR RENT

Offices for physician and dentist; three rooms, near four large schools. Rent: $45 per month; 1st month free. Chas. F. Bruess, 1201 Rice St., St. Paul, Minn.

WANTED—Position as hospital laboratory technician or physician's office assistant. Experience and good references. Address D-151, care Minnesota Medicine.

Vol. XIV DECEMBER, 1931 No. 12

MITRAL DISEASE IN ADULTS*

Henry L. Ulrich, M.D.
Minneapolis, Minnesota

ACUTE rheumatic fever is not a killer. If it affects the valves of the heart it usually cripples. The postmortem statistics of the Department of Pathology at the University show that the highest death rate for acute rheumatic heart disease occurs in the second decade; for unhealed valve defects, in the fourth decade; for healed valve defects in the fifth decade. One patient in four or five with mitral valve disease lives to the fifth decade or beyond (Levine,[2] Boas,[3] Cabot.[4] Another point of interest is that many of these cases have a long latent period, twenty, thirty or forty years, before symptoms which lead to death appear. Like so many entities which have a long chronicity or latency, they drift into an age zone, in which degeneration processes begin to manifest themselves. The associated complications which arise in mitral valve disease in the adult are not so clearly understood nor appreciated. The most common of these which lead us into difficulties are: (1) auricular filbrillation; (2) hypertension; (3) hyperthyroidism; (4) pulmonary arteriosclerosis.

Auricular fibrillation is the most common complication and most easily recognized. It occurs in other conditions such as coronary disease and hyperthyroidism. Sixty per cent of all patients with mitral valve disease eventually develop fibrillation. Its effects on the integrity of the heart, and its treatment are so well known we will not dwell on it. Suffice it to say that it is the one intrinsic cardiac factor, that is arising in the heart itself, and that it usually accompanies one of two other complications of which we will speak, *i.e.*, hypertension or hyperthyroidism.

It is in the fifth decade that hypertension usually manifests itself. It is reasonable to suppose that a certain number of patients with mitral valve disease and attaining that age will develop hypertension. Of a hospital population of 762 patients with mitral disease, 159 (21 per cent) lived into the fifth decade or beyond. Of these 159 cases, 58 per cent had hypertension (Levine[2]). In a dispensary population in the fifth decade with all types of complaints, 50 per cent had hypertension (Weatherby[5]). The closeness of these figures justifies the assumption that hypertension complicating mitral valve disease is an inheritance of the years. If we compare Levine's figures of hypertension in mitral disease with any other disease entity in the same decade the manifestation of hypertension in mitral disease is most striking. Levine, in his discussion of the subject, brings out the point that hypertension in mitral disease is a salutary symptom. The increased pressure on the left heart increases the aperture of the stenosed valves by dilatation and hypertrophy of the left ventricle. And again the increased pressure on the left side permits an easier adjustment of the balance between the two ventricles. For which reasons he thinks hypertension is a factor in the longevity of these patients. Personally I am not in accord with this assumption. In the cases I have seen, the inception of this complication has simply added another load to the heart and thereby hastened rather than retarded decompensation. The factor of longevity in a given case lies somewhere else.

I have been impressed with the number of patients with mitral disease who manifest symptoms of thyroid intoxication. While this is prevalent in women patients it is seen at times in men. There are no statistics on this form of complication. In my own experience it is more commonly found in the fourth decade. The "thyroid heart," toxic adenoma masquerading as heart disease, is well known and better recognized than formerly—but heart disease (mitral defect) with thyroid symptoms is exceedingly difficult to adjudicate. The difficulty here lies in the fact that the symptoms may be larval in character. Again the expression of the thyroid intoxication may be limited to one organ, the heart. And, once more, the basal rates are not particularly increased (Morris[6]). In fact, basal rates in these cases must be carefully weighed, for an increase may be present due to dyspnea. This picture of cardiac irritability and unstable vegetative system in mitral disease has intrigued me so much that whenever I have had no success with rest and digitalis I suspect a thyroid complication. A trial with Lugol's solution, or even thyroidectomy, is justified.

---

*Clinic on Heart Disease given at the State Medical Meeting, Minneapolis, May 7, 1931.

The fourth complication, pulmonary arteriosclerosis, is still more obscure, both in its clinical and pathological awareness. By pulmonary arteriosclerosis I mean the senile changes in the pulmonary artery in contradistinction to primary sclerosis, which is a specific entity and which is a true arteritis. Senile changes in the pulmonary artery and its branches are seen in a group of different conditions, one of the commonest being mitral disease. It is assumed that the increased work of the right heart puts a strain on the pulmonary vessels which induces the senile changes. Dilatation of the larger vessels with sclerotic plaques is usually found. If the changes are sufficient in amount (macroscopic) the physiological function of the lesser circulation is diminished, adding another link (cyanosis) to the chain of deficiencies in an impaired circulation. We have no statistics in this department on how often pulmonary arteriosclerosis accompanies mitral disease. Consciousness of this defect is comparatively new, both clinically and pathologically. Ljungdahl[7] in 1915 published postmortem studies of twenty-five mitral cases of different ages; all of them showed varying degrees of sclerosis, nine being marked (macroscopic).

The difficulty in discovering this condition clinically is much greater than at the postmortem table. Occasionally one can see the dilated pulmonary vessels pulsating during a fluoroscopic examination. On physical examination a cyanosis which occurs long before dyspnea, has been suggested as a sign. I am led to believe that an accentuated systolic bruit heard all over the chest and the expansile pulsation of the lungs felt between the ribs on palpation may be clinical criteria of value. These findings are so new, however, that I am mentioning them in a tentative way.

CASES

The first case I wish to present is that of a colleague, and because of this he is not present here in person. He is about fifty years old. About two years ago he noticed dyspnea and irregularity of the heart. Up to this time he had not known of any symptoms referable to the heart nor was he ever conscious that he had a heart. He had worked very hard as a country practitioner earlier in his life and gave no history of rheumatism.

His heart silhouette is that of the mitral type and his esophogram shows marked enlargement of his left auricle. At this time, he was fibrillating and his bood pressure was within normal limits. We encountered difficulty in reducing his rate by rest and digitalis. There was a good deal of bronchial irritability and much sweating. His basal rate was +17. Not until we gave him Lugol's solution did his heart quiet down. He returned to work.

Nine months later he again suffered from cardiac decompensation. Besides his fibrillation his bood pressure had now risen to 180 systolic and the diastolic was hard to evaluate. Another course of rest, digitalis, and Lugol's has brought him back to compensation, but his hypertension persists. His second series of X-ray plates show that the heart has enlarged in lateral diameter 1.5 cm. from the previous readings. Here is a man who never gave a history of rheumatism, who lived to be 48 years old without manifestation of heart disease, who no doubt has had a mitral heart for years, and who now has auricular fibrillation and hypertension.

The second case is a woman thirty-three years old. She has not been feeling well for about a year. During this period she has noticed nervousness, palpitation, gas in her stomach with belching. She is emotionally unstable. There is loss of about 20 pounds in weight since December, 1930. She gives a history of rheumatic fever at the age of thirteen and again at twenty-one. She is married, has four children, the youngest seven. There was an acute attack of some infection in March, 1931.

There is definite mitral disease demonstrated by the physical examination and X-ray silhouettes. There is cardiac irritability manifested by tachycardia, and an unstable vegetative nervous system. In the lower pole of the right lobe of the thyroid a definite nodule can be made out. Her heart is regular. Her basal rate is normal. She had been at the hospital three weeks under rest and digitalis without any results. The addition of Lugol's to her treatment has changed the picture materially. She is now less irritable, her heart rate has slowed down, and the additional tachycardia which manifested itself when someone entered the room has disappeared.

This woman will be sent home with instructions to take Lugol's solution at intervals. If this does not control the situation, a removal of the adenoma will be done.

The next case is a young woman twenty-seven years old who entered the hospital on the orthopedic service to have a bunion removed.

Six days after her entrance and four days after the operation she had an attack of paroxysmal tachycardia with marked cyanosis, which morphine relieved. She gave a history of having had periodic attacks of palpitation, dyspnea on exertion, and edema of the ankles of moderate degree. There are pelvic deposits, with a history of two miscarriages. The heart symptoms have been present for fourteen years. There is no history of rheumatism, but much tonsillitis. Her physical examination suggests mitral disease and the X-ray plates of her heart confirm these findings. There is a mitral bulge and a moderate impingement of the left auricle on the esophagus. But, what is more interesting, on fluoroscopic examination, it was found that her pulmonary vessels were pulsating way out into the mid-lung areas. She presents, too, the physical signs which I have mentioned—a systolic bruit all over her chest and an expansible pulsation in the intercostal spaces. We expect to learn a great deal from this patient about pulmonary arterio sclerosis.

The last patient I wish to show does not belong in this group at all.† She is shown, however, because she was sent in from the State Sanatorium to settle the question whether she has tuberculosis, heart disease and hyperthyroidism.

She is the type of case of which there is one or more in every community. Her complaint is weakness, fatigability, dyspnea and palpitation, undernutrition, lack of appetite, pain in left chest over the heart, diarrhea (six stools a day), and some pain in the lower abdomen. She describes her condition exactly when she says, "I am not well, nor am I sick." There is cough, no positive sputum, but she has had eight to ten blood tinged sputa. She has been at the Sanatorium for seven years. Two years ago we studied her and decided she had fibrotic pulmonary tuberculosis, mild mitral disease, and possibly tuberculosis of the cecum. At the present time we have decided she has a minimal amount of tuberculosis and no mitral disease.

There are murmurs over the heart but they are extrinsic in origin—possibly due to a slight displacement of the mediastinum caused by pleuro-pericardial adhesions. She is markedly underweight and suffers from neuro-circulatory asthenia. Her basal rate is not increased. The factor which to my mind is underlying a good deal of her symptomatology is her diaphragm. Her diaphragm is very low. Because of its low position,[8, 9] the circulatory function of the organ is severely impaired, producing dyspnea, palpitation, and fatigability. With an increase in weight and a suitable pad which will increase her intra-abdominal pressure the diaphragm will go up and thus restore the circulatory efficiency of the organ. While the patient has tuberculosis, its minimal quantity and its lack of progress over these seven years make me believe the diaphragm is more important in her symptom-complex It is this finding, so readily overlooked, which made me make the statement, "There is one of this type in every community."

In closing I wish to reiterate that in any adult mitral disease which does not respond to rest and digitalis—look out for one or all of the complications I have mentioned today.

---

†This case is brought into the discussion with the full knowledge of how a digression weakens one's theme. I take this risk for the sake of calling attention to an organ whose clinical and physiological concepts are little known.

TRICHOMONAS VAGINALIS VAGINITIS*

Russell J. Moe, M.D., and W. A. Coventry, M.D.
Duluth

THE frequent occurrence of *Trichomonas vaginalis* vaginitis has activated an interest which has now reached its peak since the discovery of the causative organism by Donné in 1836. By establishing a practice of examining microscopically all cases of vaginal discharge and irritation and to look especially for *Trichomonas vaginalis*, we have been appalled at the number of cases in which we find this organism. Still more pleased are we with the results we have obtained from the line of treatment we have instituted.

The organism, *Trichomonas vaginalis,* is a protozoan flagellate which is typically pear-shaped, but may be ovoid, spindle-shaped, or irregular. At its anterior end there are free flagella, usually four in number. An undulating membrane extends backward about one-half the length of the body and an axostyle projects from the posterior end. The size varies from 15 to 25 microns in length and 10 to 15 microns in width. It attracts one's attention, when seen under the microscope, by its peculiar jiggling motion which is a distinguishing characteristic.

In obtaining a specimen, the discharge is collected on the long blade of a non-lubricated bivalve speculum and a small portion transferred to an ordinary glass slide. One drop of warm normal saline solution is added and a cover slip applied. Examination under the high dry lens of the microscope will then easily and readily reveal the presence or absence of the organism. Its jerky but progressive motion is exceedingly characteristic. There will also be seen in the field numerous leukocytes, squamous epithelial cells and bacteria.

The exact mode of infection is unknown at the present time, but the possibility of contamination from the intestinal tract has been suggested by a number of writers. However, recent investigation by Bland, Goldstein and Wenrich indicates that the *Trichomonas vaginalis* is definitely distinct from the other species of *Trichomonads* found in man. That the organism has been difficult to culture on mediums that proved to be very favorable to the other *Trichomonads* would also indicate that the vaginal type belongs to a different species.

The clinical picture of this form of vaginitis is characteristic. There is always a vaginal discharge which is accompanied in 75 to 80 per cent of the cases by an irritation or itching about the external genitalia. The discomfort is quite marked and the patient often is relieved, temporarily, by taking a douche. Another finding which is suggestive is the appearance of the discharge. Typically it is thin, foamy, not at all tenacious, greenish yellow in color, and the odor is rather characteristic and disagreeable. In the non-irritating case one finds the discharge to be thicker, not foamy, creamy yellow in color and the odor less pronounced. There are, however, varying grades between these two types of cases. Many patients complain of symptoms merely for a few days just preceding or following the menstrual period. In the characteristic case with the above symptoms one is negligent if he does not look for *Trichomonas vaginalis.* At the same time one is often surprised to find the organism in a patient who does not present the classical symptoms.

Severe cases present a roughened vaginal epithelium with small elevated points which bleed rather easily, especially when touched with gauze or cotton. The vaginal walls and tissues adjacent to the introitus are hyperemic and present very much the same picture as seen in acute gonorrhea. There is no doubt but what many cases of *Trichomoniasis* have been treated as Neisserian infections because of the marked similarity in the appearance of the acute cases.

The incidence of simple *Trichomonas vaginalis* vaginitis with lesions of the cervix and neighboring organs is interesting. It has been our observation that cervical erosions are not common and are not a factor in the production or the presence of this type of vaginitis. In the treatment of a *Trichomonas* infection it is not necessary to treat an accompanying cervical erosion *per se.* However, after the organism has been eradicated from the vagina the cervical condition may be treated properly by cauterization methods. We have had one case of accompanying cystitis in which catheterized specimens of urine revealed the *Trichomonad.* We have not been able to recover the organism from the stool. Greenhill reports a number of cases in which he has done insufflation of the tubes in the presence of *Trichomonas vaginalis* without any untoward effects. The danger of spreading the infection higher up in the genital tract apparently does not exist.

---

*From the Department of Gynecology and Obstetrics, Duluth Clinic, Duluth, Minn. Read before the annual meeting of the Minnesota State Medical Association, Minneapolis, May 6, 1931.

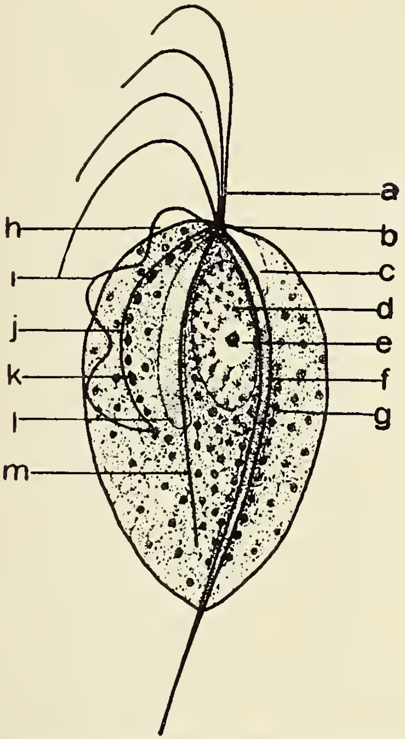

Fig. 1.—Diagrammatic representation of Trichomonas vaginalis combining the characteristics that have been revealed by different methods of staining: *a*, anterior free flagella; *b*, blepharoplast; *c*, cytostome; *d*, nucleus; *e*, caryosome; *f*, axostyle; *g*, chromatic granules along the axostyle; *h*, undulating membrane; *i*, posterior flagellum forming margin of the undulating membrane; *j*, chromatic basal rod; *k*, chromatic granules along the chromatic basal rod; *l*, sausage-shaped part, and *m*, fibrillar part of parabasal apparatus. (Drawn by D. H. W.)

Fig. 1. Trichomonas vaginalis, after D. H. Wenrich, Ph.D.

The number and variety of treatments that have been proposed indicates that as yet no specific treatment for this condition has been found. Most any treatment which destroys the organism and thoroughly cleanses the vagina will produce satisfactory results. Our treatment consists of what we have termed a "pressure douche." The office procedure is a very practical one and requires no expensive equipment. Home treatment consists of the application of a few well known principles properly handled. We have tried a number of treatments that have been recommended heretofore and have discarded them largely because of the discomfort to the patient and because they do not, in our opinion, accomplish what we believe to be the underlying principle of all treatment, namely, that every portion of the vagina must be reached in order to properly exterminate the organism. We believe that we have accomplished this by what we call the "pressure douche."

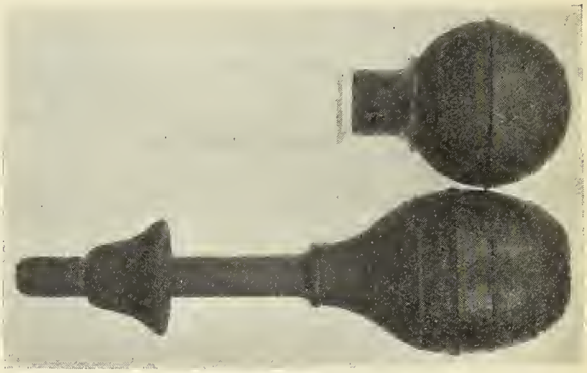

Fig. 2. *(Upper)* Glass douching syringe (Capacity 120 c.c.), blunt tip and rubber bulb. *(Lower)* Douching syringe with movable flange (Capacity 180 c.c.).

In the office treatment, which is always the first treatment instituted, the patient is placed in the lithotomy position on a bed pan with the knees up in stirrups. The external genitalia and vaginal orifice are cleansed by mopping with an antiseptic solution; oxycyanide of mercury (1:2000) or lysol (0.5 per cent). Following this a 120 c.c. glass syringe with a blunt tip and rubber bulb or an ordinary douching syringe is filled with the same antiseptic solution. The blunt point is held firmly against the introitus; the rubber bulb is then compressed, forcing the solution into the vagina, which becomes so distended that the folds and rugæ disappear and the solution comes into contact with the entire surface. By releasing and reapplying the pressure on the rubber bulb the solution may be "swished" back and forth between the syringe and the vagina. This procedure is repeated with clean solution several times until the vagina is thoroughly cleansed. The syringe is then filled with 4 per cent silver nitrate solution, which is injected into the vagina and held under pressure for a period of three minutes. There is a slight discomfort after the silver nitrate injection, but it is immediately relieved by washing the vagina again with the first antiseptic solution.

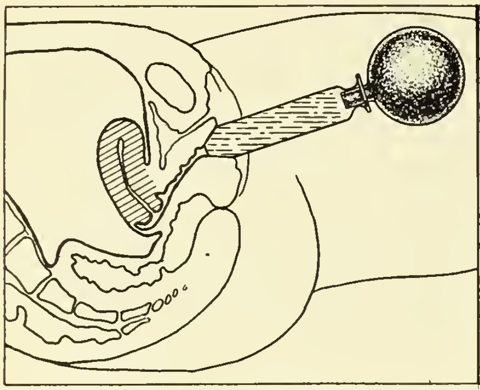

Fig. 3. "Pressure douche." Glass syringe containing antiseptic solution held firmly against the introitus.

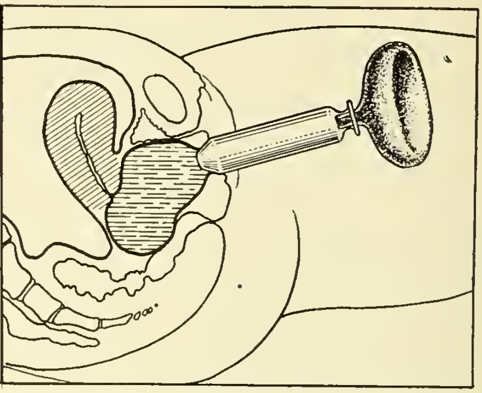

Fig. 4. "Pressure douche." Rubber bulb has been compressed, forcing solution into vagina, producing a distending or ballooning effect.

Home treatment attempts to accomplish what we have instituted at the office, that is, the "pressure douche." By holding the lips of the vulvæ firmly about the douche point, the vagina is thoroughly distended four or five times instead of taking a continuous flowing douche. The patient is also instructed in matters of anal hygiene.

Theoretically, one thorough treatment should effect a cure. We have found that practically all smears are negative after the first treatment and the itching and discharge are greatly relieved. So striking is the latter that some patients believe that they are cured and do not report for further treatment, only to return later with a reappearance of symptoms. Therefore we have been a little more insistent than usual that they follow up the initial method of treatment that we have outlined, namely, to report once a week for treatment at the office and to take a daily douche at home. They may be discharged after two consecutive negative smears have been obtained, with instructions to report again three or four days after their next menstrual period.

During the past eighteen months we have treated 95 cases of *Trichomonas vaginitis,* 68 per cent of which have been cured, 15 per cent are under treatment at the present time and 17 per cent have been referred to their home physician or have not returned. Four cases were associated with pregnancy and were treated by the "pressure douche" method. We do not believe that the incident of pregnancy need make any difference in the treatment of the vaginitis. One case of especial interest occurred in a twenty-four year old virgin with a cribriform hymen. All the classical symptoms were present. Smears taken from the vulva revealed no organisms, but the symptoms were so characteristic that we felt justified in insisting on smears being taken from the vagina itself. Under gas anesthesia this was done and the vagina was found to be filled with a foamy material which was literally teeming with *Trichomonas vaginalis.* One patient had been advised to have a complete hysterectomy, in order to control this intensive itching and discharge. A few treatments of the local condition cured her. A number of patients had cauterization treatments to the cervix without any relief of symptoms, but were completely cured by the treatment of the vaginal cause of the infection. A few patients were previously diagnosed as gonorrhea because of the profuse discharge. Examination of the discharge revealed *Trichomonas vaginalis* and proper treatment readily effected a cure.

Before presenting the slides I wish to make this plea—that all cases of vaginal discharge be studied more intensively. By this intensive study more cases of *Trichomonas vaginalis* will be found, proper treatment instituted and the patients will be cured of a very distressing and discomforting complaint.

SUMMARY

In treating a patient with a vaginal discharge, *Trichomoniasis* must be considered in the realm of probabilities. It is very prevalent, the mode of transmission of the infection being unknown. The history and clinical picture are characteristic and typical, while the method of diagnosis and the recognition of the organism present no unusual difficulties. The "pressure douche" is a satisfactory method of treatment and will cure practically all patients if properly carried out. This method is safe, effective, simple and inexpensive, and is described here in the hope that it may prove as valuable to others as it has to us. Pregnancy is not a contra-indication to treatment by the "pressure douche" method. The writers report 95 cases of *Trichomonas vaginalis* vaginitis, 68 per cent of which have been cured, 15 per cent are under treatment at the present time and 17 per cent have been referred to their home physician or have not returned.

TREATMENT OF SALPINGITIS*

William H. Rumpf, Jr., M.D.
Saint Cloud, Minnesota

THE keynote of the treatment of salpingitis, used in the broad sense of pelvic inflammatory disease, is conservatism. A small minority of cases will require operative or radical measures to effect cures. Even in these patients preservation of function should temper surgical enthusiasm.

The pelvis is peculiarly well adapted to defend itself from bacterial invasion. The rich blood supply, the extravagant lymphatic system and the functional downward drainage of the genital tract are the Marines of defense. They are, however, not incorruptible. For, when venereal disease, careless parturient handling, or the organisms from other sources enter, the very nature of its anatomic structure promotes rapid spread of infection yet retaining the inflammation within itself. The heavy uterus and appendages tend to become displaced backward within the pelvis and Nature tries to wall off the infection from the abdominal cavity. Therapeutic efforts should be supportive. The less original the method, the more coöperative will the physician find Dame Nature!

Statistics reveal that the gonococcus is responsible for 75 per cent of cases of salpingitis; 20 per cent are produced by the other major pathological bacteria of postpartum, postabortal or blood-borne sources; while the tubercle bacillus is charged with about 5 per cent of cases. Prophylactic measures may be considered properly at this time.

Gonorrheal salpingitis is a self-limited disease. Recurrent attacks are practically always reinfections or the result of secondary pyogenic invasion. Unless the vulvovaginal and cervical glands are freed from the gonococcus, reinfection is not only possible, but is adequately assured. The nasal tip electric cautery is the outstanding instrument of therapeutic destruction. I have had some success in injecting an 8 per cent mercurochrome ointment through a blunt hypodermic needle into Bartholin's duct, putting the needle in before attaching a small syringe.

The obstetrical mortality and morbidity rates, as far as sepsis is concerned, are the most convincing arguments for less meddlesome midwifery. There seems to be no way to compel the abortionist to complete the "cure" he started. The current depression has not affected this group. There is hope that the exanthemata will disappear, and this source of infection be minimized. Tuberculosis, too, is being conquered.

Acute and subacute pelvic infections should be treated expectantly. These cases are literally hot. The surgical principles of the appendix are not applicable to an acutely inflamed tube. Conservative treatment means helping nature localize the infection in the pelvis and build up an immunity against the bacterium. It means saving organs and preserving their proper function. The patient should be in bed and remain there until the infection has had time to cool off. Elevation of the bed or patient tends to prevent the spread of the infection upward. An ice bag or cold pack across the lower abdomen is comforting to the patient. Fluids should be forced and a bland diet maintained. Bowel elimination is encouraged by low enemata and mild saline catharsis. Pain is relieved by the coal tar derivatives and by pantopon if necessary. Fresh air is essential. After the diagnostic bimanual examination when cervical and urethral smears are taken, no further pelvic manipulations are advisable unless complications are suspected by persistence of fever over nine or ten days. Coitus or courting are forbidden. Foreign protein injections are usually beneficial during this stage.

Post abortal and puerperal streptococcic infections are most serious and often fatal. If blood culture reveals the hemolytic variety, various intravenous bacteriacides, such as metaphen, are recommended, or antistreptococcal sera also have their place. Small repeated blood transfusions are of definite benefit. Operations are always menacing in this type of "concrete-filled" pelvis.

A regime of palliative expectancy will permit the subsidence of the acute process in the majority of cases. An elevated temperature after ten days is indicative of complications or pus collection. Abscesses of this type should, of course, be drained. The vast majority can be well emptied by the vaginal route. A posterior colpotomy with insertion of a self-retaining drainage tube after pockets have been broken up with the examining finger, is the operation of choice. Occasionally, the drainage of pus collections higher in the abdomen by the abdominal approach is necessary. There is no other place for surgery in dealing with acute salpingitis.

---

*Read at the annual meeting of the Minnesota State Medical Association, Minneapolis, May 6, 1931.

Invalidism produced by chronic infections manifests itself in dull heavy pains across the lower abdomen which are accentuated during menstruation. Metrorrhagia and leukorrhea are usually present. The findings of a retroverted uterus with pelvic masses, and the history, substantiate the diagnosis. If the physician has confidence that good results are obtainable by noninterference, the patient will reflect that attitude and will have the courage and desire to give the conservative treatment several months trial, in a hospital, if possible.

Heat in this stage is beneficial and comforting. Dry heat from one of the standard bakers having banks of lights reflecting the heat downward over the lower abdomen is efficacious. Moist heat from prolonged hot douches is an efficient means of producing absorption of inflammatory masses, if the infection has quieted down. By a long hot douche, I mean the use of a minimum of five gallons of a weak potassium permanganate solution as hot as the patient can stand it (usually at 115 to 118 degrees Fahrenheit). This is allowed to run in slowly to consume twenty to thirty minutes. The patient should be lying down either in a bathtub with the hips elevated somewhat, or on the examining table. Makeshift arrangements can be made at home. I have cheap metal pails prepared with an outlet pipe to fit the ordinary fountain syringe tubing for use at home. The pail holds three gallons and may be filled twice. Many of my farmer patients put such an outlet on a milk can, and utilize it later as a shower bath for the children. I also have an outfit for office use connected directly with the plumbing.

Besides local treatments of the cervix, occasionally the trial of vaccine therapy and foreign protein injections has a place. I have not been an enthusiastic advocate of these measures. Diathermy has a limited field in the chronic types in the absence of any pus.

General and supportive measures to build up the patient by a nourishing diet, fresh air, ultraviolet rays, iron and arsenic, liberal exhibition of potassium iodide, tonics and cod-liver oil are, in my opinion, of greater value than most of the so-called, therapeutic conservative aids.

When the temperature has remained normal for several weeks, and does not rise with repeated pelvic examinations or hot douches; when the leukocytic counts shows a normal or nearly normal level; when the sedimentation of erythrocytes shows the normal rate of twelve or more hours; when the general condition as to blood pressure, cardiac and renal function does not contraindicate, it is proper to think of an operation, provided the patient has not recovered under really conservative treatment.

There are other factors that one must consider when the decision to resort to surgery is reached, such as the question of sterility. There are many instances of marital infection particularly of the gonorrheal type with definite pyosalpinx when conception has occurred as long as fifteen years later. There can be no other explanation than that of healing with restored tubal patency. Indeed, many of these tubes can be blown open by transuterine insufflation or the obstruction located with lipiodol salpingography. A conservative operation as salpingostomy is indicated in this type. The psychical effect of menstruation is important, and its preservation sought. Radical operators occasionally lose sight of this factor. A thorough examination under anesthesia will very often result in postponement of operative measures. It may suggest cauterization for endocervicitis to relieve a lymphangitis which on examination without anesthesia may simulate a salpingitis. Rectal or bladder pathology or the symptoms referable to poor posture and visceroptosis may cloud the picture. Complete examination will save possible embarrassment to the hasty surgical technician who rushes in and discovers only an innocent oviduct. The trained gynecologist makes good use of the rectal examination, speculum examination and examination under anesthesia.

Granted that conditions and symptoms warrant operation, the method will depend upon the findings, the age of the patient and the nervous temperament of the individual. Most patients requiring laparotomy have a combination of ovarian, uterine, and pelvic peritoneal involvement with extensive adhesions to coils of bowel. The young individual should be given a chance for future pregnancy even if it is very meager. To remove the uterus completely will, of course, abolish menstruation. If the patient has this function preserved, the psychological shock will be reduced, and menopausal symptoms delayed or lessened, which would not be the case if complete pelvic extirpation were carried out. The more high strung the woman the more imperative it is to conserve organs, and the function of one ovary at least should be saved. Resection of portion of an ovary is in the main not satisfactory, and often leads to retention cysts requiring secondary operation. A boggy infected uterus is better out although defundectomy of the Bell-Beuttner (or other) type with preservation of some endometrium has much to recommend it from the standpoint of continuing menstruation. The simple removal of one or both tubes is best accomplished by complete wedge shaped excision of the uterine horn, rather than to leave this often infected tubal portion. Hysterectomy is seldom required, therefore. Estes and others have advised transplantation of sections of the ovary into the cornuæ with the odd hope of pregnancy. I have had one case of conception follow this type of operation, which prompts me to continue the practice.

Replacement of the retroverted uterus should be done with peritonealization by an anterior pleating of the fundal portions of the round ligaments. A modified Baldy-Webster shortening again will give some support to the remaining ovaries as well as hold the uterus forward.

Pelvic tuberculosis, however, requires less conservatism, for, as Reuben Peterson and others have shown, better end-results follow radical removal of pelvic organs if the primary focus is not too extensive. The more tuberculous foci that can be removed, the better are the chances for ultimate cure of the patient. If less radical procedures are chanced, the cessation of menstruation by means of partial castration doses of X-ray will aid immeasurably in the cure.

J. V. Ricci reported in the New York State Journal of Medicine, January 1, 1928, a comparative study of three 200 case groups of salpingitis to show the value of conservative treatment. In 200 cases of acute non-operated salpingitis, there were no deaths; in 200 operated cases of the chronic non-purulent variety, there was one death; while 29 deaths were present in the series of 200 operated cases of acute and chronic disease. This last group also was forced to stay in the hospital an average of three months as against two weeks for the non-operative and an average of three weeks for the chronic cases that were operated upon.

The gynecologist has recognized the superiority of the conservative treatment of salpingitis for years, has preached it, and has been gratified at the trend in the past few years away from radical, unnecessary and dangerous operations. There are a bare 15 per cent of cases of salpingitis that require operation, and it is hoped that preventive measures can reduce this to a lower percentage. Surgery has no place in the treatment except the opening of abscesses, until the infection has had time to cool off. In the small percentage of cases requiring symptomatic interference, conservative surgery should be practiced, to preserve reproductive functions. Salpingitis, per se, should be treated palliatively, expectantly and conservatively.

HISTORIC REVIEW OF AMERICAN AND ENGLISH LITERATURE ON VITAL CAPACITY*

WILLIS S. LEMON, M.D.
Rochester, Minnesota

AMONG the major functions of the body, respiration received only late attention, and knowledge regarding its physiology was slow and much interrupted in growth. A beginning was made in the seventeenth century by the work of Boyle, Mayow, Descartes, Lower and Hooke. Mayow came very close to the discovery of oxygen, and really formed an accurate estimate of the relationship between muscular work and increased respiratory action.

Priestley and Lavoisier, by brilliant work in the discovery of oxygen, really laid the foundation for all future physiologic effort in this direction. Bonili, in 1679, was the first who tried to determine the volume of air in the lungs and he made an experimental study of the amount of air received by a single inspiration. Jarvin, in 1718, noted differences in quantity not only in different persons but in the same persons at different times. Hales, in 1728, made specific measurements of the amount of air in the lungs, and was the first to ascertain the force brought to bear in breathing by using a mercury manometer. Goodwyn, in 1788, first estimated the amount of the residual air. Keill, in 1708, made correct cubic measurements of the air exhaled from the lungs. The fundamental knowledge was now available for Hutchinson's study on vital capacity, and his was a model for even modern research.

FUNDAMENTAL INVESTIGATIONS

Hutchinson acquired exact knowledge of the work of all previous investigators, not only on the same subject, but also on subjects relating to physiology of the circulation and to the composition and pressure of the atmosphere. He seems also to have been the first to develop a fundamental conception regarding the relationship existing among the several parts of the body. He wrote: "Our structure is like a complicated machine, each portion bearing a certain relation to another, just as the wheels of a clock do to the length of the pendulum; for every length of pendulum demands its own peculiar train of wheels so calculated as to number its oscillation; this oscillation regulates the whole machine. In like manner, the respective development of every man is regulated by some certain and constant capacity or measure of his digestive system as absolutely essential to his respective development. One of the fundamental rules in architecture is 'proportion,' the relation that the whole fabric has to its constituent parts, and which each part has to the complete idea of the whole, for in buildings that are perfect in their kind, from any particular part, an architect may form a tolerable judgment of the whole; just in like manner, the physiologist, from a portion of the viscera, say an organ, should be able to form a tolerable judgment of the whole man from whom it was taken."

Hutchinson's first lecture was given in 1844 on the subject of vital statistics, embracing an account of a new instrument for detecting the presence of disease in the system. He gave the name spirometer or breathmeter to this instrument. He conceived the idea that practitioners of medicine might be benefited if they could by any means measure accurately the volume of air breathed out at one full expiration, together with the power exercised by the muscles of expiration and inspiration concerned in the effort. Before he arrived at any conclusions, or made any report on his work, he had examined more than 1,200 persons of different classes and occupations. He found that tall, thin men had the greatest vital capacity, and this fact led him to make the measurement of height the chief consideration in his observations. He believed that no other physical sign could be so steady a guide as that of height, because it does not vary in disease or in health, in adult life or in old age, although weight and breadth vary at all periods of life. His invention of the spirometer made the easily determinable vital capacity the central point in spirometry until the time of Bohr, half a century later (Lundsgaard and Van Slyke).

---

*From the Division of Medicine, The Mayo Clinic, Rochester, Minnesota. Submitted for publication May 19, 1931.

Hutchinson, in his first paper, in 1846, arranged the quantity of air in the thorax under different conditions that are dependent on thoracic movement, under five heads as follows: (1) residual air, (2) reserve air, (3) breathing air, (4) complemental air, and (5) vital capacity. To the last three divisions combined, being the greatest voluntary expiration following the deepest inspiration, the term vital capacity is applied; that is, the sum of the reserve air, breathing air and complemental air is equal to vital capacity.

As already observed, various measurements had been made but Hutchinson seems to have been the first to estimate the limits of the quantity of air under each of the five conditions that are dependent on thoracic movement. He laid down the first rules regarding standards of measurement so that estimated normal amounts of air might be compared with actual spirometric readings in health and disease. His investigation led him to inquire into the influence not only of height, which he considered his most accurate standard, but also weight, volume of thorax, circumference of thorax and sitting height and the influence of these factors, in determining the vital capacity. He came to the conclusion that the healthy vital capacity is chiefly affected by height, weight, and age, and he determined quantitatively the amount of variation that each brings about.

Not only was this study concerned with relationships affecting persons who were in good health, but also with similar relationships in persons who were ill. Hutchinson was the first to make a systematic study of the vital capacity in tuberculosis, of both early and advanced stages. He was able to anticipate the presence of pulmonary disease long before the most skilled clinicians could discover it by clinical methods then employed. In the period between 1846, when Hutchinson's paper appeared, and the beginning of the present century, papers were published by observers who either agreed or disagreed with Hutchinson, or who employed modifications of his instrument. I have been able to obtain sixteen articles written in this time.

Pepper considered the influence on vital capacity of mobility of the thorax and measured the difference in inspiration and expiration; he compared the capacity of healthy, robust, well developed active men, with that of small, feeble, underdeveloped persons living sedentary lives. Jackson and Lees also were concerned with the influence of muscular development on vital capacity. Pepper was the first to announce the effect of heart disease on the vital capacity, and noted that debility of patients with heart disease was insufficient to account for the large percentage of reduction in vital capacity. He then paved the way for the work of Peabody, which was to appear seventy years later. Pepper also confirmed the value of the spirometer in the early diagnosis of tuberculosis. He found that the degree of reduction in vital capacity corresponded with the greatest amount of pulmonary disease. It was observed that reductions in vital capacity consequent on injury to pulmonary tissue were increased by extrapulmonary conditions, such as enlargement of the stomach, liver, or spleen, and lesions that inhibited the movements of the wall of the thorax and of the diaphragm. General principles, therefore, regarding the cause of reduction in vital capacity were in the process of formation.

Schneevoogt and Voorhelm examined 300 men and women, some of whom were normal, and others of whom were diseased, and reported thirteen series of observations. They studied the vital capacity of healthy men and healthy women, of patients whose family history contained records of death from tuberculosis, of patients suspected of having tuberculosis and of others in various stages of the disease. They also tabulated results of examination of patients with pneumonia, emphysema, heart disease and deformities of the thorax, and were the first to recognize that the complications of pneumonia might be anticipated by a lowering of vital capacity when it should be rising. They failed to note the very great loss in vital capacity in pneumonia, and failed to point out the value of that fact in differential diagnosis. They also inquired into the effect on vital capacity of abdominal distention due especially to ascites and pregnancy, and were the first to give accurate figures representing the degree of loss in vital capacity, due to these causes.

Fabius added his observations of vital capacity after labor. His was the first voice raised in objection to Hutchinson's standard. He offered instead the measurement of the torso and the circumference of the thorax. However, Fabius agreed with former authors regarding the influence of age and muscular power, and the effect of tuberculosis. He added his own figures showing the reduction brought about by asthma, and by such abdominal disorders as constipation. In commenting on the efficiency of spirometry and the standard employed, Biegel wrote: "Simon, who has made many careful investigations, was of the opinion that the length of the thigh influences the amount of respiration. Fabius, however, found enormous disproportions." Biegel said: "By means of such numerous investigations as were made by Hutchinson, we might possibly find out a certain rule of proportion, and arrive at definite conclusion provided we could compare the ears, or any other part of the body, and amount of respiration of many thousands of men." This recalls the fundamental concept of Hutchinson which permitted him to establish his facts; namely, that the amount of respiration in man is in proportion to the height of his body, that the greatest respiratory power is found between the ages of twenty and forty years, and that with men of this age, for each centimeter of height, between 22 and 24 c.c. of air of expiration might be calculated, but for women the amount would be only between 16 and 17.5 c.c.

Gleitsmann, in 1874, began the first survey to evaluate the spirometric readings in relation to practical use. He studied applicants for life insurance who on examinations, by all means then available, were found to be without evidence of disease, yet whose spirometric readings were more or less palpably divergent from the calculated normal. He advocated use of the spirometer for life insurance examinations, because he believed that those with definitely decreased respiratory capacities were more likely than others to have tuberculosis, or to develop it later, and that they should not be accepted without reservation. These were the applicants who induced, in the examiner's mind, increased caution in passing judgment on their future health.

At about the same time, 1875, Elsberg and many other observers began thorough search for measurements that might permit normal figures to be established that would satisfy all the variables of age, sex, size, muscular development and strength, and the variations which occurred in disease. Elsberg's work is the first I have found that deals with the vital capacity of childhood. Waldenberg's work had already been reported. He considered the effects of inspiratory traction as well as of expiratory pressure, and thought them to be the products of various factors, some of a positive, some of a negative, nature. These factors are (1) muscular power; (2) elasticity of the lungs, and (3) obstacles presented by the walls of the thorax, its contents, and the neighboring viscera. These general principles led to studies of tuberculosis, emphysema, asthma, bronchitis, diseases of circulatory organs, asthenic states, and diseases of the central nervous system, especially progressive muscular atrophy and bulbar paralysis. Observers of that epoch were the first to consider dyspnea in relation to vital capacity, and urged spirometry as a means of denoting dyspnea with exactitude, both quantitatively and qualitatively, and as a means of showing whether it is inspiratory or expiratory or both.

Holden, like Gleitsmann, searched for practical applications of spirometry to diagnosis and treatment, and advocated its use to develop capacity of the thorax and to redilate cells that were collapsed and weakened by disease. It would seem that he used his specially devised instrument in much the same way as the instrument by which bottles are blown, but he had a musical instrument incorporated, the note of which was an index of the power employed.

By the close of the nineteenth century, largely through the stimulus provided by the investigation of Hutchinson, standards for development of normal readings had been set up. These took cognizance, especially, of the relationship of vital capacity to height, length of trunk, circumference of thorax, weight, sex and age. The observations included not only normal persons, but those who suffered from all manner of diseases. Decreases in vital capacity could be said to be due, as Peabody reaffirmed many years later, to: (1) anything which interfered with respiratory movements of the thorax, including muscular weakness, calcification of cartilages, arthritis, pleurisy, pleural effusion, and intra-abdominal conditions which might prevent free descent of the diaphragm, such as ascites, tumors and pregnancy; (2) inflammatory and infiltrative lesions affecting the pulmonary substance, such as pneumonia, tuberculosis, bronchiectasis, and carcinoma; (3) alterations of elasticity of pulmonary parenchyma, such as is produced by emphysema, and (4) increased pressure in the pulmonary circulation, and engorgement of the pulmonary vessels, such as occurs in cardiac decompensation with congestion of lungs, infarction, and effusion.

These authors of the nineteenth century employed the test of vital capacity to supplement physical examination, and expected it to show the presence of disease before examination could be expected to discover a lesion. They also employed it to determine the course, progress, prognosis and treatment of disease. Finally, they encouraged its use as an economic method for selection and observation of applicants for the Army and to exclude the unfit from the risks accepted by insurance companies.

OBSERVATIONS FROM 1900 TO 1930

Judging from the accurate and complete records that had been made by earlier observers, and their hearty endorsement of this method of examination, it would have been reasonable to expect enthusiastic continuation of work in the present century. The opposite was the case. Whatever the cause for lack of interest, whether there was a reaction from over-enthusiasm, whether there was dissatisfaction from inability to develop a standard measurement to embrace the many variable factors encountered, or whether because of the development of newer and accurate means of diagnosis, such as the roentgen ray, the test fell into disuse. About physiologic laboratories the spirometer became the spinning-wheel in the parlor; it was interesting to look at and blow into as a test of muscular strength but it was not seriously employed either in studying disease or in developing respiratory physiology.

In 1910, however, the spirometer was again of service in the examination of applicants for enlistment in the Army. Owen was of the opinion that the spirometric readings gave a more exact determination of physical fitness and pulmonary capacity than other measurements then in use, particularly that of expansion of the thorax. He also found that the liability of error was much less with the spirometer than with the tape measure.

The study of the vital capacity became universally stimulated in the years following 1913, when Hoover, Peabody and Wentworth, McClure and Peabody, Lundsgaard, Barker and Van Slyke began their studies on respiration. Their work led them to investigate acidosis in nephritis, the effects of carbon dioxide in the inspired air on patients with cardiac disease, the minute volume and alveolar air in pulmonary emphysema, the basal and the minute volume of the respiration of patients with cardiac disease, the mechanical factors in the production of dyspnea in cardiac disease, the relationship between vital capacity and dyspnea and between the size of the thorax and of the volume of the lung. Christie and Beams employed spirometry in the study of the relationship of position to orthopnea. The practical value of these studies seems to be found in the conclusions especially regarding emphysema and diseases of the heart. Hoover expressed the belief that in emphysema the patient suffers from impaired alveolar ventilation of the lung and not from impairment of the lung as the organ of external respiration.

Peabody developed the generalization: "Patients with cardiac and cardiorenal disease, who are without acidosis as indicated by the alveolar carbon dioxide tension react in a manner similar to normal subjects. Patients with cardiac and cardiorenal disease with acidosis are much more susceptible to the carbon dioxide in the inspired air. Dyspnea is more easily produced than in normal subjects or in patients without acidosis and the ventilation may be doubled when the inspired air contains only 2 or 3 per cent carbon dioxide." Not only was vital capacity indirectly involved in scientific studies of the respiration but it became very practically connected with the clinical study of heart disease, the evaluation of the stages of the disease, of progression and retrogression, of competency and incompetency. It became apparent that changes in vital capacity antedated any objective evidence of cardiac insufficiency such as pulmonary edema, enlargement of the liver or peripheral edema. The increase in vital capacity indicated improvement in cardiac competency before it could be appreciated by physical examination and a chart of many readings gave a graphic picture by which the clinician might see the whole course of the illness with respect to disturbance of the pulmonary circuit. No method in use at that time told so much about it as the determination of the vital capacity of the lungs.

Lilienthal, in 1926, in studying the comparative value of various operative procedures on the thorax, used vital capacity as an index of the crippling effect of these operations on respiration. He studied especially the vital capacity following lobectomy, and concluded that the ability to work or to exercise violently depended more on the condition of the heart than on vital capacity and thought there were far too many variations and individual differences affecting the readings to make them very important. He concluded: "From the surgeon's point of view, a reading approaching normal should not be considered as important as the elimination of the signs of disease for which the patient sought aid."

Powers, in 1928, studied the significance of vital capacity in relation to postoperative pulmonary complications. He believed that the greatest reduction of vital capacity, and the most prolonged period of recovery, followed operations on the upper part of the abdomen and he suggested that this excessive reduction in vital capacity might have some bearing on the frequency with which postoperative pulmonary complications occur after operations in this region.

Spirometry and Surgery.—The most important contributions of spirometry to surgery began in 1918, with the work of Graham and Bell, whose classical study of open pneumothorax, and its relation to the treatment of acute empyema, was the stimulus required to alter the whole plan of procedure in the surgical treatment of pleural exudates of synpneumonic type and of streptococcal origin. As a corollary of this epochal work in treatment, they were able to state general principles dealing with the risk of operation, the degree of dyspnea, and the accompanying cyanosis. These principles were to the effect that danger of operation increased in the proportion that vital capacity was reduced to the amount of the tidal air, which is the amount required to maintain aeration of the blood.

Yates, in 1925, studied vital capacity in relation to intrathoracic treatment and virtually confirmed the work of Graham and Bell. He stated: "Limitation in any of the four factors, volume of ventilated air, total expanse of alveolar epithelium, total area of vascular endothelium or unit volume of good blood, reduce the essential function, external respiration, which is manifested by corresponding reduction in vital capacity." He expressed the belief that accurately controlled observations of vital capacity of surgical patients, before and after operation, serve as a satisfactory criterion of their general postoperative condition.

Lemon and Moersch, in 1924, studied the converse of this problem; namely, the vital capacity in relation to operative risk. In view of the fairly accurate estimation which vital capacity gives of physical fitness, it seemed possible that operative risk might be estimated by the same method. They examined 379 consecutive patients before operation, compared the observations with the outcome of the operation, made a corresponding comparison with the surgeon's estimation of operative risk, and concluded: "For routine purposes, the determination of the operative risk from the surgeon's opinion is probably on the whole a more satisfactory estimate than that obtained by means of the vital capacity readings. However, if the surgeon does not have the benefit of experience or the assistance of an experienced internist in making such an estimate, especially in questionable cardiac or pulmonary conditions, vital capacity determinations may be of the greatest aid. From whatever cause, the closer the approximation of vital capacity to tidal air, the graver will the risk become."

Re-opening of investigation regarding the measurements necessary to create normal standards.—When Dreyer's book appeared in England, in 1920, the whole question of standard measurements was reopened. This study was the first real attempt to correlate all the important and accepted determining factors, such as, height, stem height, weight, age, sex and surface area. The other investigators who took part in this work included West, Lundsgaard and Van Slyke, Lundsgaard, Schierbeck, Stewart, Myers, Peabody, Boynton, Rogers, Lemon and Moersch, Jackson and Lees, and Swan and Evans.

Moersch and I have been impressed with the comparative accuracy of all the methods suggested. We believe that no single standard is applicable to all the variable factors. In that respect, we think the test is comparable to such functional tests as the test for renal sufficiency with phenolsulphonphthalein, or the various tests of hepatic function. We are also of the opinion that series of readings are more important than a single reading and that the discrepancies become of less significance if one standard is uniformly applied. For practical use, and for simplicity, one may employ the method and the tabulated data of Myers, or the slightly more bothersome calculation of West's formula. There seems to be a more nearly uniform opinion that West's formula, which includes the three great determining factors of height, weight and sex, is the most accurate. West found that the average vital capacity of young men is approximately 2.5 liters for each square meter of body surface, and that that of young women is approximately 2.0 liters for each square meter. Moersch and I thought that the vital capacity could be calculated more accurately by this formula than by any other method. West's second formula (height in centimeters multiplied by twenty-five for men and by twenty for women) seemed to us to be a satisfactory working formula, although slightly less accurate than the former. The method of Peabody and Wentworth was next in order of accuracy.

In any of these estimations, allowance must be made for age. A guide to the influence of age may be had from the work of early authors, especially of Hutchinson, and particularly from the long continued observations of Pratt, who found that vital capacity reaches its maximal amount in the third decade of life, and falls slightly in the fourth, but that no considerable reduction occurs before the age of sixty years. Bowen, in 1923, studied the relation of age and of obesity to vital capacity. He found that the vital capacity is within normal limits up to the age of fifty years; thereafter reduction is gradual and reaches 50 per cent of normal at the age of eighty-five years. The greatest drop is between fifty and sixty years. The vital capacity of people who are obese and overweight is but slightly less than normal, using the standard of height, but averages 20 per cent less than normal on the basis of surface area, between the ages of twenty-six and fifty. One of the most important studies had to do with estimations of vital capacity of children. Present knowledge in this field is largely dependent on the work of Emerson and Green who found that a close relationship exists between the vital capacity and surface area in childhood, that the vital capacity of girls is generally larger than that of boys, and that determinations of vital capacity of children who are less than seven years of age are unreliable.

Edwards and Wilson expressed their thought that the vital capacity of children exhibited slightly better correlation with height than with weight or surface area.

Stewart studied the vital capacity at various ages and traced the relative increase in both boys and girls as they grew toward maturity. He made an important observation that the increase in vital capacity becomes rapid about the time of puberty, and then proceeds at a slower rate, reaching its maximal amount near the twentieth year in the boy's life and slightly before this time in the girl's life. The period of acceleration in the rate of growth in pulmonary capacity begins and terminates at an earlier age with girls than with boys.

The report of Stiles and Graves is not unlike that of Stewart. Stiles and Graves found that there is an annual average increase in the pulmonary capacity, from the age of six years to that of seventeen years, and that this increase becomes especially marked from the age of fourteen years to that of sixteen years. The average pulmonary capacity, as measured by a dry spirometer, averages about 100 to 200 c.c. higher in boys than in girls from the age of six to thirteen years. At the age of fourteen years a very greatly increased difference in pulmonary capacity becomes evident in favor of the boys, and this difference increases between the ages of fourteen and seventeen years inclusive. At the age of seventeen years, the difference between boys and girls is marked. Stiles and Graves also studied the effects of infestation with intestinal parasites of various kinds, including Ascaris, Lamblia, *Endameba coli* and whipworm; only patients with whipworm infestation suffered any appreciable decrease from normal vital capacity.

Stewart, and Stewart and Sheets, studied the influence of disease on vital capacity and the importance of the test in estimating both the progress of the disease and the degree of injury to both the lungs and the heart. Included in their survey were cases of tuberculosis, bronchitis, lobar pneumonia, bronchial asthma, and heart disease. The moderate reduction in vital capacity present among children who had tuberculosis or were suspected of having it, was thought to be due, in part, to their general malnutrition, and probably to the presence of enlargement of tracheobronchial lymph nodes. The former explanation seemed the more probable. The conclusions lead one to believe that the effects of tuberculosis or of changes that arouse suspicion of its presence are not unlike those in adults. Wilson, Edwards, and Liss in 1924 used spirometric readings as an aid to the diagnosis of tracheobronchial adenopathy in children between the ages of five and twelve years. They found a reduction in vital capacity of 15 to 42 per cent in this type of disease.

Stewart and Platou reported that 75 per cent of children have vital capacity equal to, or more than, 90 per cent of the average for persons of corresponding age and size. Only 25 per cent have readings 10 per cent below their estimated normal values. It is to this group that special study should be directed to eliminate cardiac or pulmonary disease. The pathologic changes brought about by these diseases immediately influence vital capacity of the lungs. The progress of the disease, with increasing or declining severity, may be traced by charting repeated spirometric readings.

Racial characteristics.—Smillie and Augustine, in 1926, studied the vital capacity of the negro. They were studying the problem of infestation with hook-worm among negro children, and one of the measurements employed in determining the physical fitness of these children was the vital capacity. They discovered that normal negro children had markedly lower vital capacity than white children of the same age, sex, and economic status. This difference was found to be so constant that it seemed to them to be a true racial characteristic. Although the negro has longer legs and a shorter trunk than the white person, yet they found that the vital capacity of the negro when calculated from surface area was not greatly different from that of the negro when calculated from standing height. When the vital capacity of negroes was calculated from sitting height, however, the result was much higher than when it was calculated from standing height or surface area. Smillie and Augustine expressed the belief that the low readings, calculated from surface area and standing height, were due to the shorter trunk of the negro. Even when calculated from sitting height, however, the readings were 15 per cent below those of comparable white people. They thought that the standard deviation and the coefficient of variation of both races are lowest when vital capacity is calculated from surface area. Because of the low vital capacity of negroes, there is the temptation to suggest that there may be a correlation between it and their susceptibility to respiratory disease, particularly to pneumonia and tuberculosis. Smillie and Augustine have no data to sustain such an assumption.

Turner and Aboushadid studied the vital capacity of Syrian women and compared it with that of English, American and German women. They found the values definitely lower among the Syrian women than among the controls. Mixed races had vital capacity more nearly corresponding with the controls. Studies by Foster on Chinese adults and by Nanagas and Santiago on adult Filipinos and Chinese also indicate that these races have smaller vital capacity than Caucasians.

Throughout the last decade, many observers have repeated the studies on vital capacity in the presence of disease, without adding any really new data to those general principles discovered by Hutchinson and those who followed his work before the beginning of the present century. Nor have any principles been added to those laid down by Peabody. An instructive observation was made by Arnett, in 1925. He found that in so-called neurocirculatory asthenia, no significant diminution of the vital capacity exists as it does in organic heart disease. This is in agreement with the work of Levine and Wilson, Adams and Sturgis, White, and others who have shown that the vital capacity is generally within normal limits among patients with an irritable heart.

Flagstad and Kollman studied the vital capacity in cases of deformity from scoliosis. They were impressed with the rarity of tuberculosis in these cases and with the frequency of cardiac disease. They found dyspnea, irregularity of cardiac action and hypertrophy of the heart in the severe cases, and believed that these patients suffered impaired health due to their deformity. The resistance, defense, growth and repair of the intrathoracic structures, as well as of the entire organism, are commensurate with vital capacity. Flagstad and Kollman expressed the belief that the vital capacity gave an index to the injury done and to the operative risk, especially of thoracic, spinal, and abdominal operations. If the vital capacity approaches 50 or 60 per cent of normal, operation should not be considered lightly. Reduction of vital capacity probably explains the shock that frequently follows operation on severely sick persons.

Within later years, Myers reopened the discussion of the value of the test of vital capacity in estimating the fitness of recruits to the Army. Dreyer pointed out its use in the British flying service and Schneider made use of the test with the American flying forces. Ferguson made some definite statements as a result of work in the American naval service. He expressed the thought that spirometry was largely without diagnostic value in heart disease, but that in pulmonary disease, particularly incipient or quiescent tuberculosis, very valuable evidence could be obtained. His results are worth repetition: "Review of the Naval Academy records showed that nineteen midshipmen had developed pulmonary tuberculosis since 1912; of these nineteen men, ten had spirometric estimations made within a year of the development of the disease; seven, or 70 per cent, of these ten men had spirometric readings below the minimum for their height, that is, below 90 per cent of the calculated normal. Those figures are all the more striking because at the time of the observation the men had chest examinations made by at least two experienced examiners and no evidence of tuberculosis was found."

The value of the test consists in focusing attention on a particular group of men. It does not replace physical examination or other accepted methods used in diagnosis.

Wittich and Polczak compared tests of breath-holding with vital capacity in health and disease. They found that the deviation from the standards set up by Stange and Sabrazes was approximately the same as the deviation from the standards of vital capacity, and that cardiac or pulmonary disease produced the same effect on the readings of either test. The group of tuberculous men and women showed definitely corresponding diminution of breath-holding and vital capacity and the values diminished notably as the disease advanced. They quoted the work of McMechan as follows: "The breath-holding test bore a definite and direct ratio to vital capacity as gauged by the spirometer, so that a normal breath-holding test would naturally suggest a normal vital capacity and any decrease or increase of the breath-holding interval would indicate a corresponding rise or fall in vital capacity. The vital capacity in cubic centimeters clinically is usually about 100 times the Stange breath-holding interval in seconds for males and the Sabrazes test for females."

The workers of the present century have been able to develop acceptable standards for estimating the normal vital capacity. They recognize that no single test can satisfy all the variable influences, any more than any single renal or hepatic test can give complete information regarding the functions of those organs.

The influences of disease and race on the vital capacity have been confirmed, and the knowledge extended. The diagnostic and prognostic value has been more nearly agreed on, and the practical value of the test in both civilian and military practice has been established.

IS VITAMIN A AN ANTI-INFECTIVE AGENT?

The significance of vitamin A as an essential of human nutrition can no longer be questioned. Until recently, physiologists have been engrossed with the consideration of the more obvious manifestations of deficiency disorders. The gross lesions of scurvy, pellagra, rickets and other results of dietary defects have received foremost consideration. When mastoid and nasal sinusitis, purulent otitis media, and ocular, respiratory and alimentary tract infections were found to occur in laboratory animals deprived of vitamin A, the problem of "lowered resistance" naturally presented itself. Recent investigation has suggested that infection may follow the weakening of the tissues, and that it may be due to the breakdown of the local tissue defenses. This has raised the question as to whether it is proper to refer to vitamin A as an "anti-infective" agent. Rats inoculated with virulent bacteria and kept on a vitamin A-free diet showed markedly decreased resistance to infection as compared with controls receiving cod liver oil. No such susceptibility to similar inoculations was found in rats on a diet deficient in vitamin D, compared to controls protected by viosterol. Increased susceptibility to infection is apparently an early manifestation of a dietary low in vitamin A. There has been a lack of evidence that vitamin A can cure infections when the barrier of the mucous membranes has been passed or that it can prevent or cure infections that enter the blood stream. The newer studies pave the way for the possibility, however, that vitamin A may after all do more than maintain the physiologic defenses of the mucous membranes. (Jour. A. M. A., October 24, 1931, p. 1229.)

THE SURGICAL TREATMENT OF ACUTE EMPYEMA*

Stuart W. Harrington, M.D.
Rochester, Minnesota

THE most common type of empyema is that which occurs as a complication of some primary pulmonary disease. Practically all cases of pulmonary infection are under medical supervision from the onset of the disease and those cases in which surgical intervention is required usually are the result of unavoidable complications that have developed during the course of the disease. The patients are very ill, for their resistance has been lowered by the primary pulmonary infection, and surgical treatment to alleviate the condition should be as conservative as possible.

The fundamental principle in the treatment of acute empyema is surgical drainage, but the time, site and method of drainage depend on the indications in the individual case. Many methods have been advanced for the accomplishment of drainage in these cases, but none has been entirely satisfactory in all cases, which explains the multiplicity of operative procedures. The majority of methods advanced differ only in details of technic. The cardinal principles of any method for cure of acute empyema are : (1) adequate drainage, (2) avoidance of open pneumothorax, (3) rapid sterilization of the diseased area, (4) early obliteration of the cavity by expansion of the lung, and (5) good medical care with particular attention to the nutrition of the patient.

Surgical intervention in these cases should be conservative, directed toward saving the patient's life, and toward restoring him to health in the shortest time, with the least loss of structure and function, and with a minimal amount of discomfort and deformity.

From an anatomic standpoint, acute empyema may involve the entire thoracic cavity, with complete collapse of the lung, or encapsulation may have taken place, and the empyema may be of the interlobar, parietal, mesial or diaphragmatic types. In these types of empyema, only a portion of the thoracic cavity is involved, and the lung is only partially collapsed. The condition may be unilateral or bilateral, and the encapsulated cavities may be single or multiple.

In cases in which physical signs, clinical symptoms, and roentgenologic examination give reason to suspect the presence of empyema, the first surgical procedure indicated is that of diagnostic aspiration of the thoracic cavity. This procedure should be carried out under the strictest observance of the laws of asepsis, and the patient should be prepared for a radical procedure if it should prove necessary. The site of election for the puncture is determined by the physical signs and roentgenologic examination. The usual site, in the total and large parietal types of empyema, is the eighth or the ninth interspace, in the posterior axillary line. If the fluid is thin and clear, or opalescent, no further surgical procedure should be performed at the time, except when there are signs of cardiac or respiratory difficulty from pressure of a large amount of fluid; then from 500 to 750 c.c. of fluid may be removed, thus completing the procedure as a therapeutic aspiration. A culture of the fluid removed should be made and the type of bacterial invasion determined; this is of prognostic importance but has no direct bearing on the subsequent operative procedures except in cases of tuberculous empyema. If pyogenic organisms are not found, either by smear or culture, surgical drainage of the pleural cavity should not be instituted, regardless of the clinical symptoms or of the gross appearance of the fluid aspirated, because of the possibility of the condition being a tuberculous effusion. When anaërobic organisms are found, great care should be exercised not to contaminate the thoracic wall, because of the possibility of producing severe gangrenous infection.

The types of bacteria which more commonly invade the lungs are the pneumococcus and the streptococcus. Of the streptococci, those of the hemolytic type are especially noteworthy. The pneumococcic type of empyema is likely to occur late in the course of the pulmonary disease, during the process of healing, and there is a tendency to early formation of fibrin and frank pus, with thickening of the pleura. The hemolytic streptococcus types of empyema usually occur early in the course of the pulmonary disease, and the formation of fibrin and frank pus, with thickening of the pleura, is less rapid. This type presents the greatest surgical risk because the empyema is present when the toxemia of the pulmonary disease is greatest.

---

*From the Division of Surgery, The Mayo Clinic, Rochester, Minnesota. Read before the Minnesota State Medical Association, Minneapolis, May 4 to 6, 1931.

During the acute, seropurulent stage of empyema, aspiration should be performed as often as necessary to relieve cardiac and respiratory difficulty. Gradual transition of the fluid, from a clear, thin appearance, to an opalescent, thick aspect, will be observed, and finally frank pus will be obtained, at which time surgical drainage is indicated.

Repeated aspiration rarely effects cure, although it may be curative occasionally in hemolytic streptococcal types. However, repeated aspiration is of great aid in tiding the patient over the critical period of the illness, until the pneumonic process is healing, and fibrinous thickening of the visceral pleura has stabilized the mediastinum. Operative drainage by one of the closed methods can then be accomplished with greater safety.

The method of choice for surgical drainage is a matter of personal experience. I have obtained the best result from the intercostal closed method and from the transcostal closed method, in the latter of which the dressing tube is inserted through the inner layer of periosteum, after resection of a small segment of a rib. The site of drainage is determined with an aspirating needle, a trocar and cannula of the desired size are inserted through the selected interspace, and a catheter the exact size of the cannula is inserted through the cannula, which is then withdrawn. In this way the drainage tube fits the opening in the thoracic wall as accurately as possible. The tube has an opening at the end, and another at the side, and enters the empyema cavity for not more than half an inch, thus preventing injury to the pulmonary tissue when the lung reëxpands to fill the cavity, and also avoiding mechanical irritation as a contributing cause of thickening of the pleura. The tube is clamped and securely fastened to the thoracic wall with adhesive tape, making an air-tight closure. The pus is aspirated with a syringe, and the cavity is irrigated at first with physiologic sodium chloride solution. Then, if a bronchial fistula is not present, 0.5 per cent chlorinated soda (Dakin's solution) is used to aid in sterilizing the cavity, in liquefying the fibrin and to act as a chemical decorticant. This procedure is carried out every hour in the course of the day and every two or three hours at night. The patient is immediately started on respiratory and blowing exercises to reëxpand the lung and to obliterate the cavity. The vital capacity is estimated daily to determine the progress of the reexpansion of the lung. A specimen of the drained material is taken for culture, and the capacity of the cavity is measured once a week.

The kind of solution used to irrigate the cavity is a matter of choice and experience. Many solutions act better in the test tube than in contact with tissue. I have tried the different solutions, and recently have studied three parallel series of cases; in one series I used mercurochrome, in a second, physiologic solution of sodium chloride, and in the third, 0.5 per cent chlorinated soda. It is difficult to make any definite decision relative to the merits of each. I believe that there is very little antiseptic value in the solutions used, and that the efficiency of the irrigation method lies in the mechanical washing out of the pleural exudate. Because I have employed the solution of chlorinated soda for a longer time, I may be prejudiced in its favor. Its greatest value in obliterating the cavities consists in its proteolytic properties and in its mechanical action on the tissues; thus the period of drainage and of convalescence is shortened. It must be used in strength so that 0.45 to 0.5 per cent of free chlorin, the active agent of the solution, is available and it should be prepared fresh. I use a solution of hyclorite, a proprietary preparation, which is about eight times normal strength, is more stable than 0.5 per cent chlorinated soda, and does not have to be prepared so often. It is prepared for use by mixing one part of the hyclorite solution with seven parts of distilled water. It is not only bactericidal but lytic in action, and, therefore, is of great value in cases in which the closed method of drainage is used, and in which there are masses of fibrin in the pleural exudate. Hyclorite cannot be used in cases of pleurobronchial fistula in which drainage has been accomplished by the closed method because it gives rise to irritative cough. In these cases, irrigation with solution of sodium chloride is carried out until open drainage can be instituted; then the solution of chlorinated soda can be used if the fistulas are plugged.

Great care should be exercised in maintaining nutrition and body fluids of these patients. They should be given a diet of high calorie value, averaging from 3,000 to 3,500 calories a day, with a liberal intake of fluid.

The intercostal, closed method of drainage is not a new method, for the underlying principle was first advocated by Bülau and was reported in 1891. The method described is a modification, with many changes in detail and subsequent treatment. In some cases the drainage may be interfered with by plugging of the tube with masses of fibrous material from the pleural exudate. This material usually can be dislodged by suction on the tube with a syringe. Occasionally there is leakage around the tube, but as a rule this does not take place for a week or more, by which time the patient has been carried over the dangerous period and marked reëxpansion of the lung has taken place. Then open drainage by costal resection can be instituted with greater safety. In the majority of cases there is no technical difficulty with drainage and irrigations, and the size of the cavity gradually decreases. This decrease is most marked in the first week or ten days, after which reduction is much slower.

When the capacity of the cavity has been reduced to 50 c.c. and very little progress occurs after two or three weeks, an open operation is performed, involving resection of one or two ribs. The residual cavity is allowed to heal by granulation, and is packed twice a day with gauze saturated in hyclorite solution, or if the cavity is large enough tubes are inserted for irrigation with hyclorite solution.

If the cavity continues to contract under the closed method of treatment, the tube is gradually shortened until the cavity is entirely obliterated. This can be done in 60 to 70 per cent of the cases, but there is danger of recurrence, and if there is a return of symptoms a tube should be reinserted immediately. It is probably a safer procedure to change to open drainage after practically complete reëxpansion of the lung has taken place, and only a small residual pocket remains, particularly if the patient is not under observation daily.

I recently reviewed seventy-one cases of acute empyema in which I have operated in the last five years (tabulation). The infecting organism in thirty-two cases was the pneumococcus Type I, in five cases the pneumococcus Type II, in three cases the pneumococcus Type III, and in one case the pneumococcus Type IV. In twenty cases the streptococcus was the infecting organism, and in seventeen of these it was of the hemolytic type. Intercostal, closed drainage was

SURGICAL TREATMENT AND RESULTS IN SEVENTY-ONE CASES OF ACUTE EMPYEMA

Types of infection	Cases
Pneumococcus Type I	32
Pneumococcus Type II	5
Pneumococcus Type III	3
Pneumonococcus Type IV	1
Hemolytic streptococcus	17
Streptococcus	13

Types of operation and mortality	Cases	Healed without subsequent operations	Subsequent open operations necessary	Deaths
Intercostal closed drainage	34	20	14	4
Transcostal closed drainage	32	24	8	
Repeated aspiration (streptococcal infection)	5	2	3	
Total	71	46 (65%)	25 (35%)	4

Data on cases in which death occurred

Cases	Age, Years	Diagnosis	Operation	Days after operation, when death occurred	Cause of death
1	65	Right streptococcal empyema	Intercostal closed drainage	29	Meningitis; myocarditis; right bronchopneumonia
2	29	Left streptococcal empyema	Intercostal closed drainage	9	Mitral endocarditis with stenosis; bilateral bronchopneumonia
3	5	Right hemolytic streptococcal empyema	Intercostal closed drainage with subsequent open operation 23 days later	40	Fibrinous pericarditis and mediastinitis; bronchopneumonia
4	1	Bilateral pneumococcus Type II empyema	Intercostal closed drainage on left side; eight days later, intercostal closed drainage right side	44	Acute serofibrinous hemorrhagic pericarditis

used in thirty-four cases. Of these, healing was complete in twenty in from three to six weeks, without further operative treatment. In fourteen cases, it was necessary to perform a minor open operation, removing a small segment of from one to three ribs to hasten obliteration of a small residual sinus or cavity holding from ½ to 1 ounce (15 to 30 c.c.). In thirty-two cases the transcostal type of closed drainage was done, in twenty-four of which healing took place without further operation and in eight of which subsequent open operation was required to obliterate a small residual cavity. Repeated aspirations were performed in five cases of streptococcal empyema, and in three of these subsequent open operation was required. In the two cases in which healing took place the infection was of the hemolytic streptococcal type. The most common causes for failure of complete obliteration of the cavity by the closed method were the presence of pleurobronchial fistula, and thickening of the visceral and parietal pleura, with fixation of the lung as a result of delayed drainage. In a few cases in which it was impossible for patients to remain under observation, an open operation was done for a small residual sinus, because of the possibility of retention of seropurulent exudate in the small sinus tract. Such retention may cause recurrence of the empyema.

There were four deaths from operation in the entire series. One patient, sixty-five years of age, died from myocarditis, meningitis, and bronchopneumonia twenty-nine days after operation. The infecting organism was a green-producing streptococcus. A second patient, twenty-nine years of age, who had bilateral pneumonia, died nine days after institution of drainage for empyema which developed on the left side and the infecting organism of which was a green-producing streptococcus. The cause of death in this case was mitral endocarditis, with stenosis, and bilateral bronchopneumonia. A third patient, five years of age, died forty days following institution of drainage for postpneumonic empyema of the right side, with pulmonary abscess. The cause of death was fibrinous pericarditis, mediastinitis, and bronchopneumonia, and the infecting organism was a hemolytic streptococcus. The fourth patient to die was a child, one year of age, who died forty-four days after institution of drainage for bilateral empyema, following pneumonia in the course of which pneumococcus Type II was found. The left side was drained first and the intercostal closed method was used. The right side was aspirated for eight days before intercostal drainage was instituted on that side. The cause of death was acute serofibrinous hemorrhagic pericarditis.

The number of deaths, three, was greatest among the cases of streptococcal empyema; among the patients with the pneumococcus type of empyema there was one death. All of the patients who died were extremely ill and death was not due to the empyema or to the type of treatment instituted for relief of the empyema, but was the result of lack of resistance against the primary infecting organism.

Forty-nine patients recently replied to letters of inquiry. In two cases the wound has not healed because of bronchopleural fistula. In one of these cases, six months has elapsed since operation. The cause of the empyema in this case was a pulmonary abscess which had ruptured into the pleural cavity. In the second case, seven months has elapsed since operation. This patient had interlobar empyema, with multiple bronchopleural fistulas. In forty-seven cases the patients were entirely relieved of symptoms, and the wounds had healed.

Inasmuch as chronic empyema is the result of gradual development from the acute condition, over a period which may be arbitrarily taken to be two or three months, it would seem that if all the factors which lead to chronicity could be anticipated, recognized, and obviated during the treatment of the the acute condition, there would not be any chronic stage, and complete healing would result. However, it is manifest that this uniformity of cases and perfection of treatment cannot exist, and in many cases chronicity is unavoidable from the onset. Such cases are those in which the etiologic factor is tuberculosis, actinomycosis, secondary involvement of the thorax from a subdiaphragmatic amebic infection, or a degenerating malignant growth with secondary infection, rupturing into the pleural cavity.

The majority of cases seen at The Mayo Clinic are of the chronic type. In reviewing the factors which led to the development of the chronic condition in these cases, it was found that the most common were incomplete drainage, collapse of the lung, secondary encapsulated cavities, pleurobronchial fistulas, foreign bodies such as drainage tubes and bismuth in the cavity, formation of calcium deposit in the empyema cavity, and osteomyelitis of the ribs as a result of secondary infection of the thoracic wall. The treatment of these cases is essentially surgical, and the operative procedure is of much greater magnitude than in the treatment of acute conditions. This emphasizes the importance of proper treatment during the acute stage of the disease.

SUMMARY

The most common types of empyema are those which occur as complications of pneumonia of pneumococcal or streptococcal etiology. The treatment of acute empyema is surgical drainage, the guiding principle of which is to be as conservative as is consistent with effectual treatment. Seventy-one cases of acute empyema are the basis of this report. Intercostal closed drainage, transcostal closed drainage, and repeated aspirations were the types of surgical treatment used. In forty-six cases (65 per cent), healing took place without open operation. In twenty-five cases (35 per cent), subsequent open operation was required, for obliteration of the small residual empyema cavity. There were four deaths in the entire series, or an operative mortality of 5.6 per cent.

THE A. M. A. CHEMICAL LABORATORY

The A. M. A. Chemical Laboratory cannot analyze specimens for individuals. 1. The chemical work undertaken by the Laboratory must be of *general* interest to physicians. 2. The laboratory is busily engaged in the work for which it was founded, namely, investigations of the newer remedies for the Council on Pharmacy and Chemistry. 3. The Laboratory undertakes examination only of products in original containers, bearing original labels and the source of which can be vouched for in case of possible court action. 4. The present Laboratory would need much enlargement and a far larger staff to examine specimens for all of the one hundred thousand physicians it is designed to serve. (Jour. A. M. A., October 3, 1931, p. 1001.)

NEW AND NON-OFFICIAL REMEDIES

There is no better way of keeping up to date on the newer remedies than to follow the work of a competent, unbiased group of scientific investigators, working altruistically in the interest of the medical profession. The Council on Pharmacy and Chemistry is such a group. New and Non-official Remedies is its list of accepted products. The book is published annually and describes accepted articles and includes facts the physician should know. It keeps physicians up to date regarding the newest remedies. It advises physicians of products not worthy of their attention. It is useful to the physician when he is importuned by the detail man to prescribe a new specialty. (Jour. A. M. A., September 5, 1931, p. 707.)

TRAUMATIC ABDOMEN*

Roy F. Raiter, M.D.
Cloquet, Minnesota

To the general practitioner or surgeon practising in an industrial section where the treatment of accidental injuries makes up a large part of his practice, the subject of traumatic injury of the abdomen is a very important one.

In this paper I shall confine myself to a discussion of the non-penetrating injuries, since the diagnosis and treatment of penetrating wounds are in most cases fairly obvious.

The importance of early diagnosis is evident for examination of reported cases reveal a mortality of 40 per cent in those cases operated upon within twenty-four hours after the injury.

The industrial surgeon seeing the patient who has received an abdominal injury must, if he is to successfully treat this patient, in a very limited time, quickly determine if the injury sustained is merely a contusion without visceral injury and which requires conservative treatment, or whether an intra-abdominal organ has been injured, requiring immediate and not delayed surgical interference. He must depend principally in the majority of cases on the history of the case and manner of injury, on what he can see and feel, and without the special aids, such as X-ray, the laboratory and so forth. In some of these cases, early diagnosis is extremely difficult, and after repeated examinations at short intervals, if symptoms and signs, as I shall mention persist, it is safer to operate in these doubtful cases.

A study of the reported cases reveals some striking facts about abdominal injuries.

1. Injuries of the liver and spleen are more common than injuries of the hollow viscera, such as the stomach, the intestine, and the urinary bladder.

2. The predominant objective symptoms in injuries of the solid or parenchymatous organs are early severe shock and hemorrhage, which cause death very early, often within a few hours, while in contrast to this, these factors or symptoms are not nearly so common in injuries of the stomach, intestines and urinary bladder.

3. A smaller proportion of patients with injury to their hollow viscera die of intra-abdominal hemorrhage and shock. In these cases death usually occurs at a later time and more often from an acute suppurating peritonitis which results from leakage of the contents into the abdominal cavity.

The reason for this relative infrequency of injury to the hollow viscera is probably due to the difference in their anatomical location and structure. The stomach is protected to a great extent by the lower ribs; the colon is lying on a cushion of small intestines, and their greater mobility enables them to more easily escape injury. While on the other hand the solid or parenchymatous organs are less free to move and their friable consistency makes them more susceptible to rupture. The urinary bladder is also protected from injury by the bony pelvis and is in danger of rupture only when in a state of full distention.

There are some general symptoms common to all of the abdominal injuries, and specific ones which present themselves according to the individual organ or structure involved.

Of the general symptoms and signs we find abdominal pain (local or generalized), shock, tenderness and abdominal rigidity common to all. A patient with serious abdominal injury commonly presents symptoms of shock, the pulse is rapid and of small volume, the temperature is subnormal, and vomiting often occurs, almost invariably in cases of intestinal rupture. Early, however, the temperature and pulse are not reliable symptoms because of the shock immediately following such injuries. Later on, with the reaction from the shock, a rising temperature and pulse and persistence of vomiting are sufficient to demand an exploration. No one single symptom or sign of visceral injury can be considered pathognomonic.

Tension of the abdominal wall is perhaps the single most important of the objective signs of an organic lesion within the abdomen, and its presence, if persistent, justifies immediate surgical intervention. This muscle tension may be circumscribed or boardlike rigidity of the entire abdomen while in a mere contusion of the abdominal wall it is rarely present, and, if present, lasts only a short time. This rigidity appears immediately after the injury and does not yield to morphine, and is the most significant of the objective symptoms.

---

*Read before the annual meeting of the Minnesota State Medical Association, Minneapolis, May 5, 1931.

Obliteration of liver dullness is an important sign in that it aids in differentiating between intra-abdominal hemorrhage and a rupture of a hollow viscus.

Free air in the abdominal cavity, demonstrable by fluoroscopic examination, is an almost constant sign of a ruptured hollow viscus such as the stomach or intestine.

Costal breathing is often characteristic of these cases. The patient should be carefully observed while in repose and if the abdominal wall is immobile while the thorax responds to deep breathing, an organic lesion within the abdominal cavity is probable.

Grassman's sign or sensitiveness of the Douglas pouch is a valuable aid in the diagnosis of injury to the abdominal organs but it is usually not positive until late and in many cases may be absent.

As before mentioned, the usual result of injury to the parenchymatous or solid organs is marked shock and profuse internal hemorrhage. One of the most commonly injured of these organs is the liver. It is much disposed to injury on account of its size, consistency and fixation.

Ruptures of the liver are of two varieties: (1) true rupture in which the capsule and parenchyma are torn; (2) subcapsular ruptures in which the lesion is produced below the intact capsule. Subcapsular ruptures are much more rare than the true variety, and it is this latter variety which gives rise to severe intra-peritoneal hemorrhage.

Graham gives three reasons why hemorrhage from the torn liver is so severe.

1. Liver blood mixed with bile coagulates slowly.
2. The hepatic blood vessels have fewer vasomotor fibers than the vessels of the other organs.
3. The diaphragmatic movements cause a continued blood pressure variation.

For these reasons spontaneous hemostasis in liver injuries is rare.

Symptoms of ruptured liver are those of internal hemorrhage and shock, abdominal rigidity, diffuse abdominal pain which often radiates to the shoulders and dullness in the flanks if the hemorrhage is severe.

In the treatment of liver ruptures one should be guided by the amount of hemorrhage. Few of these cases can be treated conservatively, and the safest procedure is operation, either suturing the tear or packing, which is the quickest and most simple. Other methods like cautery and compression of the hilus and ligation of bleeding points are time consuming and more difficult.

An illustrative case of liver injury.

A man, aged 48, was brought into the hospital at about ten in the morning from a saw mill where he had a few minutes previously been struck in the upper abdomen by a kick-back board. He was in great constant pain, marked shock, with a rapid pulse, and had an anxious facial expression, extreme rigidity of the entire abdominal wall, costal breathing and marked upper abdominal tenderness. A diagnosis of the liver or intestinal perforation was made and he was operated two hours after entrance to the hospital. A tear along the falciform ligament was sutured with a blunt needle and the hemorrhage stopped. A drain was inserted and the abdomen closed. Convalescence was uneventful and he was discharged sixteen days later.

One point worth mentioning is that in suddenly opening an abdomen in which there is a bleeding organ such as the liver or spleen, sudden release of intra-abdominal pressure may cause a renewed profuse hemorrhage where hemostasis has partially taken place.

Injuries of the kidneys vary from a simple contusion to a complete tear of the kidney parenchyma. Hematuria is the usual and most constant symptom with pain in the loin, spasm of the lumbar muscles, and sometimes abdominal rigidity. Although some of the severest ruptures manifested by continued intense hematuria and signs of internal hemorrhage, occasionally call for a nephrectomy, even the largest perinephritic hematoma will often be absorbed or at the most require incision if it becomes infected.

A patient illustrating an example of moderate kidney injury was brought into the hospital after a car collision.

The patient stated that he had been forcibly thrown against the arm rest in the rear seat of the car. He complained of pain in the loin which was constant. He was passing bood-stained urine and was tender to palpation only on the affected side in the loin. He was not in shock, the pulse rate was about normal, and he had no other symptoms. He was put to bed and given morphine, and continued to pass blood in the urine in decreasing amount for two days. The pain and tenderness gradually lessened and patient was discharged on the tenth day.

The urinary bladder is injured more commonly in men, probably because of more frequent exposure to violence. The tear may be extra- or intra-peritoneal. The former can give rise to a spreading pelvic cellulitis, the latter causing a pelvic peritonitis. The extra-peritoneal are almost invariably associated with fractures of the pelvic bones, while the intra-peritoneal are caused by contusion to the anterior abdominal wall when the bladder is distended.

Injury to the bladder is evidenced or characterized by a constant desire to urinate, but the patient is able to pass only a few drops of blood-stained urine. Catheterization most always yields a small amount of bloody urine. When an injection is made into the bladder of a measured amount of sterile water, the amount returned will usually be less, unless the tear in the bladder is very large and the catheter passes through the bladder into the abdominal cavity, when the return may be much greater than the amount injected. Ruptured bladders should be repaired immediately and drainage instituted.

The following case report is that of a federal prisoner who fell out of a top bunk in his cell onto the cement floor, landing on his abdomen. He was brought into the hospital shortly after. He was in moderate shock, complained of constant burning pain over the lower abdomen with a constant desire to urinate. Muscle rigidity was present over the entire abdomen, more marked over the lower half. A catheterized specimen yielded only a small amount of almost pure blood although he stated that he had taken several glasses of water two hours before and had not voided since. A diagnosis of ruptured bladder was made. He was operated on about two hours after entrance to the hospital. The lower abdomen and pelvis were filled with a large amount of bloody urine. A tear about one inch long was found in the posterior wall of the bladder. The hemorrhage had stopped by this time. The rent in the bladder was repaired, a retention catheter was placed in the bladder, a drain in the free pelvis and the abdomen was closed. After running a stormy course for one week with a moderately severe peritonitis, his condition improved and he was discharged one month later.

In the intestinal injuries, hemorrhage is usually not so common a factor unless the mesentery is torn, when bleeding can be very severe. Shock may or may not be present, vomiting is almost always present, pain is usually present, as is also abdominal rigidity, and these, if persistent and increasing, together with obliteration of liver dullness following a history of injury to the abdomen, are very important in the diagnosis of intestinal rupture. Shock, which is so early a symptom in liver and spleen injuries, is often absent in intestinal injuries. Rising pulse, increased temperature and abdominal distention are of value only later when peritonitis develops.

Case reports show that early operation for intestinal and stomach injuries is the best method of treatment. If the perforation is small, closure is not difficult, while, with larger openings and tearing of the mesentery, resection of part of the bowel may at times be necessary.

A case quite typical of above was recently observed. A male, aged 46, was admitted to the hospital at 11:45 A. M. He had been struck a sharp blow over the lower abdomen by a spring lever. He complained of severe abdominal pain, vomited several times, and was in moderate shock. The pulse was slightly elevated but strong, his temperature normal. The entire abdomen was tense, the liver dullness not obliterated, and Grassman's sign was absent. With persistent muscle rigidity, continued vomiting and increasing abdominal pain, operation was decided upon three hours later. Upon opening the abdomen through a lower midline incision, the abdominal cavity was found to be badly soiled with intestinal contents. There was a small amount of blood and a beginning peritonitis. In the lower ileum about six inches from the ileocecal junction, a single perforation was found. The rent in the bowel was closed, free fluid and intestinal contents sponged out as well as possible, drains inserted and the abdomen closed. The patient died on the sixth day following operation from a generalized suppurating peritonitis.

Injuries to the spleen are not uncommon. The extent of ruptures and tearing of this organ varies. The hemorrhage is usually severe, early shock is marked, pain may be diffuse or localized in the upper left abdomen with tenderness and rigidity over the splenic area. Where the hemorrhage is severe immediate splenectomy is demanded. Only in the minor tears should suturing or packing of this organ be employed.

Injury to the gallbladder is a very rare occurrence and to the pancreas even more so. Early jaundice as well is peritonitis follows injury of the gallbladder. In injuries of the pancreas shock is immediate and severe and peritonitis develops early. The treatment is early operative intervention with repair and drainage.

In conclusion I wish to again point out that in an individual with a history of injury to his abdomen, and in whom the above mentioned signs and symptoms of visceral trauma are persistent or increasing, immediate operation is demanded without waiting for more specific data.

Tension of the abdominal wall is perhaps the single most important of the objective symptoms of an organic lesion within the abdomen. Its presence, if persistent, justifies immediate surgical intervention.

PANTOPON-ROCHE OMITTED FROM N.N.R.

Pantopon-Roche (Pantopium Hydrochloricum), marketed by Hoffmann-La Roche, Inc., is a mixture of the hydrochlorides of the alkaloids of opium containing 50 per cent of anhydrous morphine hydrochloride. The Council on Pharmacy and Chemistry reports that it was accepted for New and Non-official Remedies in 1915 and that, in accepting the product and repeatedly thereafter, the Council has insisted that the firm avoid in its advertising any claim that Pantopon-Roche is possessed of essential properties lacking in morphine. The Council was obliged, however, to remind the firm that its advertising should not contain this claim either directly or by inference; and the firm repeatedly signified willingness to abide by this condition. Recently a circular letter of Hoffmann-La Roche, Inc., was forwarded to the Council by a physician. The intent of this letter to indicate that the action of Pantopon-Roche is essentially different from that of morphine was plain. Furthermore, the letter failed to apprise the physician of the identity of the product, namely, that it is a mixture of the hydrochlorides of opium alkaloids. The Council concluded that Hoffmann-La Roche, Inc., could not be depended on to market Pantopon-Roche with claims which make it acceptable for New and Non-official Remedies and therefore rescinded the acceptance of the product. TREATMENT OF PARANASAL SINUSITIS*

E. R. Bray, M.D.
Saint Paul

THE treatment of sinus disease may be divided into prophylactic treatment and treatment for acute, subacute, and chronic sinusitis. In this paper I wish to emphasize the prophylactic treatment. The nose and sinuses are lined by a very delicate mucous membrane which is well supplied with blood vessels and covered with fine cilia. These cilia in health keep up a continuous to and fro movement which tends to remove foreign particles and excessive secretion from the nose. This action together with the slightly antiseptic action of the mucous secretion tends to free the nose of infection. Any injury to the mucous membrane breaks down this line of defense and allows infection to spread to any part of the nose or to any of the sinuses.

Among the common causes of injury to the mucous membrane of the nose are: sleeping in poorly ventilated rooms and living in over-heated buildings where no means of moistening the air are maintained; irritating gases or vapors; air filled with dust particles, and, to those who are susceptible, certain pollens or other allergic irritants. Another common cause of injury to the mucous membrane of the nose is the long continued use of nasal sprays or ointments or the habit of drawing up watery solutions through the nose under the false impression that they will prevent disease or cure a dry nose. We often use mild sprays in disease conditions over a short period of time but they should never be continued indefinitely. A better way to build up an immunity against nasal infection would be to take regular out-door exercise every day, summer and winter, combined with a varied diet including such foods as milk, butter, fresh vegetables, and fruits, meat or fish once a day and only a limited amount of carbohydrates. Cod liver oil and calcium should also be added to the diet of any one who is subject to nasal discharge or sinus infection. Any good brand of cod liver oil rich in Vitamins A and D is, as a rule, preferable to the more concentrated substitutes.

Proper clothing also is a factor in promoting freedom from respiratory and nasal difficulties. Loose garments sufficient to keep one warm but not enough to cause excessive perspiration are preferable. If one requires wool undergarments to protect against the cold, the wool should be mixed with linen or cotton to absorb the moisture.

Exposure to cold or dampness does not necessarily bring on respiratory disease. The fisherman or hunter or soldier may tramp through a cold drizzling rain all day, sleep in a cold tent at night and feel no ill effects from his adventure.

The treatment of acute sinusitis is the same as for acute coryza. If the symptoms are severe, this should consist of rest in bed, light diet, some alkaline cathartic, hot drinks, mild astringent spray for the nose and some sedative for headache. Surgery is strongly contra-indicated during this stage, as nature has not walled off the infected area, and immunity against the invading organism has not been established. As the pain is caused by pressure from within the sinus, after its natural opening is swollen shut, immediate steps should be taken to relieve this swelling. Pledgets of cotton dipped in 10 per cent argyrol or 1 per cent solution of ephedrin may be placed in the nose and allowed to remain for half an hour, after which mild suction may be used. This can be repeated in three or four hours if necessary for pain. Radiant heat, such as the infra-red lamp, used for half an hour immediately following this treatment, will give beneficial results. The patient should lie on his well side while the radiant heat is being used, to facilitate drainage. Strong ephedrin solution should seldom be used in the nose as the congestion which follows its long continued use is worse than the original swelling. After a sinus infection has lasted four or five days some immunity has been established and mild surgical measures may be considered. If an antrum is the sinus infected and is still causing pain it may be irrigated with warm boric or weak salt solution through a puncture made under the lower turbinate. Place a pledget of cotton moistened with

---

*Read before the Minnesota State Medical Association, Minneapolis, May 6, 1931.

10 per cent cocaine under the turbinate ten minutes before making the puncture. If pus is present in the return flow of the irrigating solution, the puncture-wound should be enlarged with biting forceps to facilitate any necessary subsequent irrigation. A biting forceps is preferable to a rasp, which may leave shreds of tissue that tend to swell and form synechia, making subsequent puncture more difficult.

After ten days we may call sinusitis subacute. Pus that continues to appear under the middle turbinate may come from the antrum or anterior ethmoids or frontals. Hirsh of Vienna says that 90 per cent of apparent subacute ethmoid infections clear up entirely after a diseased antrum has been cured. If a swollen middle turbinate interferes with the drainage it may be infracted. A cystic middle turbinate may have its outer walls caved in to improve drainage. A subacute ethmoid or frontal infection will usually clear up after improvement of drainage at this point. If ethmoid infection and pain continue, it may be necessary to exenterate the ethmoid cells. The Pratt method is the operation of choice, where the work is done under the middle turbinate and the turbinate is not sacrificed. Where the frontal sinus is involved, breaking through the anterior wall of the anterior ethmoid is done at this time. This gives a much better drainage for the frontal sinus than through its natural opening alone. Any attempt to enlarge the natural opening to the frontal with a rasp would only court disaster, as the opening, denuded of its mucous membrane, would soon close and a much more serious condition would follow.

Sinus infection that continues for a month or more may be called chronic. Chronic sinusitis may be divided into the simple chronic, hypertrophic, hyperplastic, purulent and empyemic forms. In the acute stage of sinusitis the cells of the mucous membrane are only swollen. In the chronic stage the cells increase in number as well as in size, forming the chronic hyperplastic stage. In chronic non-purulent sinusitis one must always be on the lookout for some allergic cause. This is the reason that operations on this form of sinusitis are often disappointing. It may be that the flour mill worker is sensitive to flour dust and the young lady who powders her nose is sensitive to some cosmetic rather than some form of bacteria. The chronic purulent hypertrophic sinusitis may also have had an allergic foundation with an infection superimposed on the original trouble. In this case not only must the drainage and ventilation be improved but the original cause of hypertrophy must be remedied if possible. In all chronic sinusitis cases obstructions must be removed with the least loss of important structures. Deviated or thickened septums should be corrected by a submucous resection. This is much better than sacrificing a portion of one of the turbinates. Chronic diseased ethmoid cells should be exenterated as spoken of under subacute sinusitis without the sacrifice of the middle turbinate. The opening to the sphenoid should be enlarged if the sphenoid sinus is involved. An hypertrophied lower turbinate may be partially fractured over toward the outer wall and held in place by a light packing between the septum and turbinate for twenty-four hours. If the soft tissues of the lower turbinate are much swollen they may be treated with a diathermy needle.

Beck, of Chicago, has devised a clever way of performing this operation. The needle is insulated except at its tip. This needle is inserted under the mucous membrane in the soft tissue along the length of the hypertrophy. The current is then turned on while the needle is slowly withdrawn and turned off before the point of the needle quite reaches the surface on its way out. This coagulates the deeper soft tissues but does not destroy the mucous membrane.

A chronic infection of the antrum will usually clear after a large window is made under the lower turbinate. Diathermy may be used in conjunction with this treatment as reported by Granger of Boston and others. Diathermy is contraindicated in acute conditions where drainage is poor but is very useful in chronic cases where drainage is established.

Where too much pathological change has taken place in the mucous membrane of the antrum the Caldwell-Luc operation may be performed. This operation should not often be necessary if other means of treatment at our disposal are used. This can also be said of the external frontal operation with still more emphasis on account of the deforming scar that remains. The empyemic form of sinusitis is a collection of pus in one of the sinuses, usually from a low grade infection. Drainage and ventilation is the treatment. A mucocele is a cyst containing mucous within a cell. No pain is present unless the cyst is large enough to cause pressure symtoms, or to obstruct the drainange of the sinus. The treatment is complete removal.

Although one may lay down general rules for the treatment of sinus disease every case requires individual treatment. Success or failure in the treatment of disease of the nasal accessory sinuses depends on one's ability to provide relief from various conditions encountered without the sacrifice of important tissues.

IS MANGANESE AN ESSENTIAL ELEMENT?

Considerable has been written of late about the possible role of copper as a "promoter" of hemoglobin formation in certain types of anemia. It appears to act as a supplement to iron in this process. A similar function has been attributed to other elements, notably manganese, though the claims are still stoutly denied by the majority of investigators. Manganese is constantly present in animal tissues and this has led to the assumption that it is likely to promote some useful purpose. Experiments have been reported in which the addition of traces of manganese to a diet of whole cow's milk supplemented with iron and copper has a favorable effect on the growth of mice, and that without manganese they failed to ovulate properly. The latter was true also for female rats. These experiments indicate that manganese may be closely connected with the reproductive organs. Other investigators also insist that manganese does not take part in blood regeneration, but that the element aids in rendering a diet complete for the support of reproduction and suckling of young. (Jour. A. M. A., October 10, 1931, p. 1078.)

SOME DENVER FRAUDS

The Home Products Company, Hormex Company, Vitatone Remedy Company, West Medicine Company and Western Medical Clinic, all indecent swindles, have been barred from the mails. Eugene P. Gurley and Robert T. Nash have been operating a concern under two trade names: Home Products Company and Hormex Company. Both were a continuance of the Vital-O-Gland Company which had previously been prosecuted. The Home Products Company was selling preparations for the alleged sexual stimulation of men and of women. The Hormex Company's nostrums were, according to the government report, substantially the same products under different labels. The Vitatone Remedy Company was similar in scope to the Home Products Company and the Hormex Company: it sold alleged cures for sexual weakness. The West Medicine Company and Western Medical Clinic sold through the mails two preparations, 909 and Brigham Young Tablets. The first was sold as a cure for syphilis; the latter as a cure for "lost manhood." Jour. A. M. A., September 19, 1931, p. 868.)

A NEW AND EFFECTIVE NON-SURGICAL METHOD FOR THE TREATMENT OF CHRONIC SUPPURATION OF THE MIDDLE EAR*

Charles Hymes, M.D., M.S., F.A.C.S.
Minneapolis

THE cure of the chronic running ear has long presented a most stubborn problem. Months and even years of treatment with the ordinary text-book methods have yielded in the vast majority of cases discouraging results. It is this fact that has led to the general opinion even among some otologists that one may recommend radical surgery in the case of a chronic suppurative ear which has not yielded to local treatment after a reasonable length of time.

Knowing as we do that the radical mastoid operation frequently fails to effect a complete cure, and complete cure in the mind of the patient means the cessation of his chronic discharge, one naturally hesitates to recommend such a procedure. When this type of operation is recommended, it should be made clear to the patient that the operation is to be undertaken in order to obviate any possibility of intracranial complications and that it may fail to cure the patient's most annoying symptom—the chronic discharge. In addition, the almost total loss of hearing which invariably follows the radical mastoid is a serious factor to be considered.

Patients suffering from chronic suppuration of both ears present a serious problem to the otologist, particularly where the hearing function has not been greatly impaired. The question arises whether to operate one or both ears. If both ears are operated upon, it virtually destroys the patient's hearing. If only one ear is operated upon, it does not safeguard the patient from a possible complication arising from the second ear. Obviously, an effective non-surgical method of treatment is the answer to this problem.

It is true that some cases of chronic middle ear suppuration are so fraught with danger of complications that there is no choice as to the method of treatment. However, in most cases serious complications do not arise. Eminent otologists are agreed that signs and symptoms indicating operation usually present a timely warning.

A consideration of the types of chronic middle ear suppuration becomes appropriate at this point, inasmuch as the proper evaluation of the signs and symptoms in any case of chronic suppurative otitis may be of such importance to the welfare of the patient.

We may classify chronic middle ear disease according to the existing perforation. The non-dangerous type of inflammation presents central perforations which may be either tubal where the perforation is located anterior to the hammer handle and the disease process is located in the eustachian tube, or central perforation where the disease process is more likely limited to the mucous membrane of the middle ear. In neither of these types of cases is surgery justified, for they seldom give rise to complications. The dangerous types are those showing either small central or marginal perforations. The small central type of perforation may be located in Shrapnell's membrane or in the pars tensa of the drum, the former frequently being associated with necrosis of the lateral attic wall and cholesteatoma and are more likely to be complicated by meningitis and temporal lobe abscess. The latter may be complicated by septicemia and lateral sinus thrombosis.

Marginal perforations may involve the entire drum or all of the pars tensa. This type of disease may be associated with cholesteatoma and may be complicated by any or all of the intracranial complications.

There are but few indications for radical surgery; these are the presence of symptoms of impending intracranial complications, cholesteatoma, which only occasionally complicates middle ear disease, and extensive bony necrosis. Bony necrosis is believed to exist in practically every case of chronic middle ear suppuration. The presence of a foul odor to the discharge serves to enhance that belief. However, after observing the disappearance of the foul odor and the subsequent cessation of the discharge with but several treatments by the method I have employed, one is inclined to believe that bony necrosis is present in some cases to only a small degree. However, when the bony necrosis is extensive or when it exists in the body of the mastoid bone itself, so that it is inaccessible to local treatment, radical surgery may be resorted to for its eradication.

---

*From the Department of Ophthalmology and Otolaryngology, University of Minnesota. Read before the annual meeting of the Minnesota State Medical Association, Minneapolis, May 5, 1931.

In that radical surgery is indicated in so few cases of chronic running ears, we are faced with the problem of finding an effective local treatment. I need not recite the older methods of treatment. Their usual ineffectiveness is familiar to us all, and this, no doubt, led to the universal practise and belief that radical surgery is the only permanent cure.

The method I have employed with marked success consists of the use of a mixture of potassium iodide crystals 25 and powdered boric acid 75. The ear is thoroughly cleansed of its secretions and the powder insufflated into the middle ear by means of low air pressure. This treatment is repeated two or three times weekly and the patient is told simply to keep the ear clean. He is not permitted to cleanse the middle ear cavity. There may be considerable smarting when the powder makes contact with the middle ear mucosa, but this passes off shortly. In the case of sensitive patients, the local application of a cotton swab saturated with 2 per cent butyn suffices to prevent any discomfort arising from its use.

The powder on dissolving in the secretions of the ear liberates free iodine, which in turn comes in immediate contact with the diseased tissues of the tympanic cavity. In that the powder when insufflated reaches every crevice of the irregular middle ear, free iodine is enabled to exert its powerful germicidal action on very portion of the tympanum.

A review of the cases treated by this method and the results obtained attests to its efficiency, which at times cannot be considered short of astounding. In some cases the discharge ceased after but one treatment, while in practically all of them a profuse discharge was changed to a scanty one almost immediately and the foul odor, which is chiefly due to the presence of bacillus fetidis, disappeared as quickly. It is seldom that more than six treatments covering a period of two weeks time are required for the cure of a chronic discharge. This stands in marked contrast to the experience of Lederman, who reports in the June, 1930, issue of the *Laryngoscope,* the results of cases of chronic suppuration of the middle ear treated with iodine dusting powder, in that the completion of the treatment of his cases requires from three to six months.

The following are case reports of patients who remained under observation until treatment was completed:

Case 1.—C. G. Age 12. History: Left ear running constantly for ten years. Since 1928 has treated regularly at the University Dispensary with no effect. Examination revealed entire pars tensa of left ear drum gone, foul discharge present. Between April 26, 1930, and May 5, 1930, patient received three treatments of potassium iodide and boric acid powder. Ear was dry on May 5 and has remained dry since. Function of left ear has improved from 10 feet for spoken voice to 20 feet.

Case 2.—Mrs. C. S. Age 42. History: Left ear running since September, 1929, following attack of diphtheria. Examination revealed large central perforation with a foul purulent discharge. First treatment on June 5, 1930. By July 8, 1930, ear was dry. When examined again on February 10, 1931, ear was still dry and had remained dry since she was last treated. Hearing for spoken voice had improved from 3 feet to 10 feet.

Case 3.—S. W. Male. Age 29. History: Running ear since 1915. Radical mastoid performed June, 1929, at University Hospital. Ear continued to discharge since operation. Ear was treated once with potassium iodide and boric powder on June 14, 1930. He was not seen again until October 2, 1930, when the ear was found to be dry, and the information obtained from the patient was to the effect that the ear dried up immediately after he received his treatment in June of 1930.

Case 4.—M. B. Female. Age 65. History: Intermittent discharge from right ear for many years. Ear has been discharging constantly for past three years. Examination revealed large central perforation. She was treated four times between April 28, 1930, and May 14, 1930, when ear was found to be dry. On February 10, 1931, she was again examined and the ear was still dry and had remained so.

Case 5.—D. G. Female. Age 17. History: Had scarlet fever at age of five months and has had discharging ears since. During past five years, ears at times would cease discharging but never for more than two weeks at a time. Examination showed marginal perforations of both drums involving entire lower and posterior half of drum. Function—each ear 18 feet for spoken voice. Whispered voice heard 13 feet in right ear and ten feet left ear. She received four treatments between dates of April 14, 1930, and April 25, 1930, when both ears were found to be dry. In November, 1930, she had a reinfection of the left ear. The ear discharged for two weeks and cleared up spontaneously. Both ears have been dry since, the right one having been dry since April, 1930. This is a case where radical surgery may still be necessary on the left ear.

Case 6.—B. J. Male. Age 17. History: Measles as a baby and has since had intermittent discharge from both ears. Examination showed left ear dry and entire pars tensa gone. There is also a perforation in Shrapnell's membrane. Right ear, entire pars tensa gone, foul discharge. Was given powder treatment between May 22, 1930, and June 2, 1930, when ear was found to be dry. Function in right ear improved from 17 feet to 23 feet for spoken voice.

Case 7.—Mrs. F. O. Age 37. History: Right ear running constantly for past two and a half years. Had all upper teeth removed and tonsils out, but no effect on running ear. Examination showed large central perforation, very foul smelling discharge. Heard spoken voice at 3 feet. Was given one treatment on January 31, 1931. When she returned on February 2, 1931, ear was found to be dry. Function for spoken voice was increased to 8 feet.

Case 8.—H. M. Female. Age 38. History: Seven years ago left ear began to run. Occasionally ear does not run so much and may not run at all for a few weeks. Lately running constantly. Examination showed large perforation in left ear extending to margin and occupying most of posterior half of drum—foul odor. Spoken voice heard at 3 feet. First treated November 10, 1930. On November 13, 1930, there was a slight mucopurulent discharge with no odor. On November 17 after second treatment her ear was dry. Spoken voice improved to 5 feet. Ear remains dry to date.

Case 9.—B. J. Male. Age 73. Constant discharge from right ear for past five years following an acute cold—foul odor. He had had considerable treatment to no avail. Examination showed pars tensa of right drum gone clear to margin. Polypi and granulations in middle ear extending from auditis. He was treated between dates of July 15, 1930, to August 4, 1930. On last visit ear was dry and has remained so. Was given treatment of boric and potassium iodide powder and two applications of 25 per cent silver nitrate to granulations.

Case 10.—G. K. Male. Age 45. History: Left ear has discharged for many years. Has had two operations on ear, the last one a radical mastoid about five years ago. Ear has never stopped discharging. During June, 1930, he received three powder treatments. On June 15, 1930, his ear was dry.

Case 11.—B. G. Female. Age 23. History: Mastoidectomy right ear five years ago. Has had intermittent discharge from right ear since. During past six months discharge has been constant. Examination showed large central perforation with foul purulent discharge. Spoken voice heard 14 feet. Treated between May 29, 1930, and June 14, 1930, when ear became dry. Function right ear improved to 20 feet for spoken voice.

Case 12.—M. K. Female. Age 17. Radical mastoid left ear three years ago—ear has been discharging since. Right ear also draining and shows large tubal type of perforation. Was first treated May 24, 1930. July 8, 1930, both ears were dry. Was seen again September 20, 1930, when ears were both dry.

Case 13.—A. K. Male. History: Simple mastoid on left ear eleven years ago. At about same time right ear began to discharge intermittently. Discharge has been constant during past six months. Treated once on October 13, 1930, after which ear became dry and has remained so to date. Hearing, spoken voice 10 feet before treatment. Improved to 15 feet.

Case 14.—H. P. Male. Age 18. History: Intermittent chronic running left ear for ten years following scarlet fever. Right ear operated ten years ago and has not troubled since. Examination showed fetid discharge from left ear—large central perforation. Received eight treatments between January 6, 1931, and February 2, 1931, when ear was dry. Hearing on this ear for spoken voice improved from 6 feet to 10 feet.

Case 15.—C. S. Male. Age 21. History: Scarlet fever at 9 years of age—right ear has discharged intermittently since. June, 1929, radical mastoid was performed on right ear. However, discharge has been constant from this ear since the operation. Received two treatments of the boric acid and potassium iodide powder, on June 11, 1930, and June 13, 1930. When he was examined on June 16, 1930, the ear was found to be dry.

Case 16.—L. P. Male. Age 16. History: Measles thirteen years ago—intermittent discharge since. At times ears are dry but never longer than two weeks. Examination showed pars tensa of both ear drums gone from marginal perforations. Hears spoken voice right ear 14 feet, left ear 1 foot. Whisper right ear 4 feet, left ear 6 inches. Treated between June 9, 1930, and July 7, 1930, when both ears were dry. Spoken voice had improved on the right ear to 18 feet and left ear to 3 feet.

Case 17.—V. R. Female. Age 18. History: Scarlet fever at fourteen months of age. Both ears have been running constantly since. Had extensive marginal perforations of both ear drums. Spoken voice heard on right ear 3 feet, whisper 6 inches. Left ear, spoken voice 2 feet and whisper 3 inches. Treated between June 3, 1930, and July 5, 1930, when both ears were dry. On July 21, 1930, she developed an acute exacerbation of the left ear with slight elevation of temperature. She was sent in to the University Hospital, where radical mastoid was performed on July 23, 1930. At operation we found necrosis located within the body of the mastoid itself. On November 6, both ears were dry, spoken voice right ear at 8 feet and whisper at 5 feet. Left ear, spoken voice heard at 3 feet, and whisper at 1 foot.

Case 18.—M. S. Male. Age 67. Has had a discharging left ear since nineteen years of age. Discharge has been constant. Examination revealed a foul purulent discharge with a double perforation extending to the margin of the drum. Was able to hear only loud noise on contact. Was treated on February 26, 1931. On the following day he returned for examination. Only a small amount of mucoid discharge was found in the middle ear and odor was gone. On March 1, 1931, ear was dry and has remained dry since. Function not improved.

Case 19.—A. B. Male. Age 11. Has had intermittent chronic discharge from both ears for past year with impaired hearing. Right ear revealed a large central perforation behind the hammer handle and a small central perforation in Shrapnell's membrane. The ear, however, was dry. The left ear showed a large marginal perforation, involving about one-third of the posterior portion of the drum with a foul, thick, purulent discharge. Hearing, right ear, spoken voice 8 feet; left ear, 3 feet. The discharging left ear was first treated on March 3, 1931. On March 4, 1931, this ear showed very little discharge and the odor had disappeared. He returned on March 11, 1931, when the ear was found to be dry after having received two treatments. Hearing on this ear was now found to be 12 feet for spoken voice.

Case 20.—S. K. Female. Age 23. History: Has had a chronic discharge from left ear since 1912. Examination reveals large marginal perforation involving the entire pars tensa of the drum. Hears spoken voice on contact. Discharge is foul and purulent. Was first treated on December 20, 1930. On December 22 the discharge was only scant and odorless. On December 23, ear was dry. Since this date, the patient has had two exacerbations, the last one having occurred on April 14, 1931, at which time there was a recurrence of the discharge and moderate mastoid tenderness. The ear is still under observation and the patient has been advised that a radical mastoid operation will in all probability become necessary inasmuch as it is believed that there must be considerable necrosis in the mastoid process itself, although X-ray shows only a sclerosis of the mastoid. The patient has accepted this advice and the ear will be operated upon shortly.

In conclusion let me state that the above cases represent a fairly average series with which we are called upon to deal. Some cases, it is noted, responded to but one treatment, some to two or three, and that a few required more. It is to be seen also that the treatment is particularly effective following the radical mastoid operation. This ought to make this method of treatment particularly acceptable, inasmuch as in the experience of the average otologist the cessation of the chronic discharge does not take place in more than half of the cases operated upon radically. Its limitations are also demonstrated in that several cases developed an acute exacerbation of a chronic mastoiditis. In one such case, the radical operation was resorted to, and it was recommended for still another.

The results obtained on the cases sighted, in my opinion, far excel results obtained by the usual local treatment of chronic middle ear suppuration. Our experience with this type of treatment offers convincing proof that every case of chronic middle ear suppuration should be offered the benefits of the non-surgical treatment described, save those where there is positive evidence of serious impending complication and where there is very good evidence that local treatment cannot possibly be permanently effective, such as in cases of cholesteatoma where the cholesteatoma cannot be removed through the external auditory canal, and in cases where necrosis exists in the mastoid body and thus is inaccessible to any form of local treatment.

CASE REPORTS

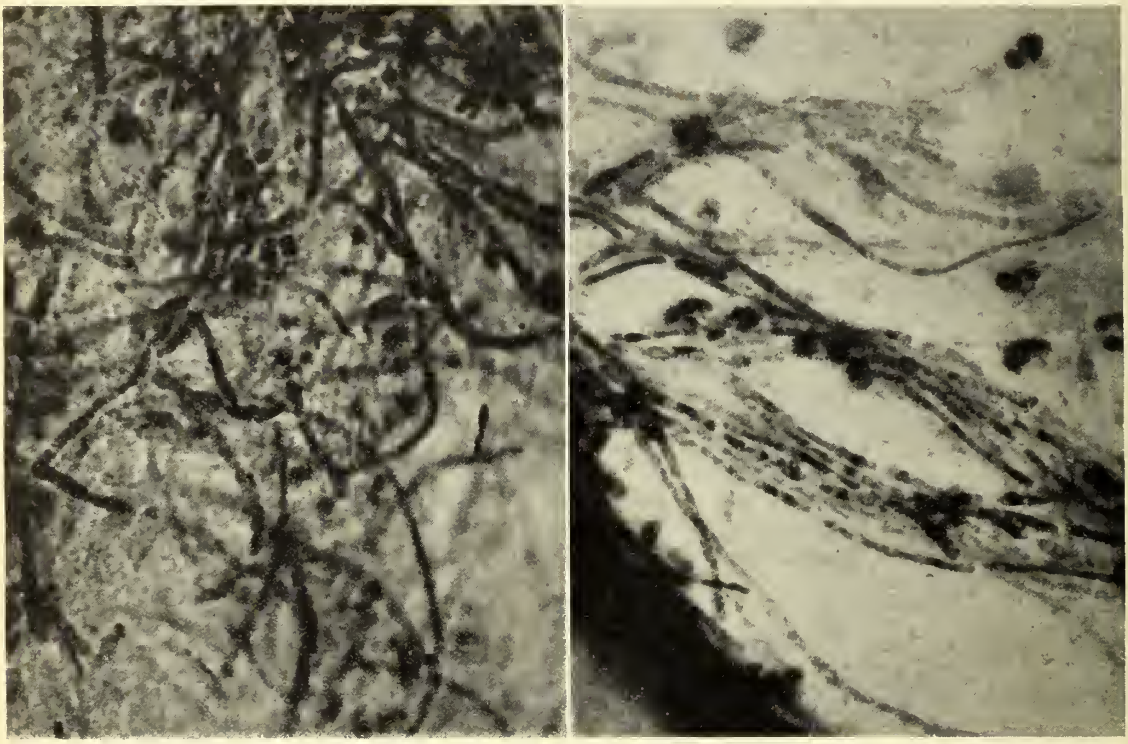
VAGINAL THRUSH

REPORT OF A CASE

Ruth E. Boynton, M.S., M.D.*
Minneapolis

Infections of the vagina and cervix with yeast-like organisms have been recognized for many years. Until recently, however, vaginal infections due to these organisms belonging to the Monilia group were considered uncommon. Plass (1) et al. have recently given a very complete review of the literature on this subject. Their own observations show that the Monilia organisms are frequently found, not only in women complaining of vaginal discharge, but also in the vaginas of women with no symptoms. The literature also brings out the fact that Monilia infections occur much more commonly in pregnant than in non-pregnant women. Since few cases of this type of vaginitis have been reported in non-pregnant women, the following case report is given:

A young woman, aged nineteen, was seen on July 22, 1931, complaining of intense itching about the vulva associated with a watery vaginal discharge which began July 18, 1931. Two days after the onset of these symptoms, she began to have a "cheesy" discharge from the vagina. She had no urinary symptoms. The patient gave a history of having had intercourse at frequent intervals for several months, the last time one week prior to the onset of the symptoms. Her last menstrual period was July 6.



Vaginal Smear—Stained with Gram's stain. Photomicrograph × 850.

A pelvic examination showed the introitus to be very red. Bartholin's and Skene's glands were not palpable. The entire vaginal wall was covered with a thick white membrane which was very adherent. The appearance of this exudate was typical of the exudate seen in oral thrush. The cervix was reddened but was not covered with the exudate. Smears showed large numbers of mycelial threads with their buds. They were gram-positive. No gonococci were present. Cultures for diphtheria bacilli were negative. Cultures for Monilia were made on an acid medium prepared by Dr. A. T. Henrici of the Department of Bacteriology and typical growths of Monilia were obtained and identified by Dr. Henrici. Urinalysis was negative.

---

*From the Students' Health Service and Department of Preventive Medicine, University of Minnesota.

On July 23, 1931, one day after her first visit, at which time no treatment had been given, the exudate was thinner and less adherent. On removal of the membrane, the wall of the vagina was markedly inflamed. At this visit, the entire vagina was swabbed thoroughly with a 1 per cent aqueous solution of gentian violet, as suggested by Moench (2), Cooke (3), and others. The patient was instructed to take douches of sodium bicarbonate the following day and return the third day for further local treatment. She telephoned that she was unable to come for further treatment, but that she had had complete relief from her symptoms from the one application of gentian violet. She has not been seen since. A communication received from her early in October stated that she had had no recurrence of any of the symptoms. Whether this patient is permanently cured cannot be predicted as these cases frequently undergo spontaneous relief of symptoms and months or years later may have a recurrence.

In this case, the typical thrush-like character of the exudate in the vagina made possible a clinical diagnosis of Monilia vaginitis which was substantiated by microscopic examination of the smears. In many cases of Monilia vaginitis, the appearance of the vagina is not so characteristic and a diagnosis can be made only upon examination of the smears. The mycelial threads and buds stain readily with Gram's stain (Gram +) and can easily be identified.

The accompanying microphotographs were taken from the vaginal smear stained with Gram's stain in this case. The characteristic mycelial and conidial forms of the organisms readily show up as Gram-positive organisms.

PULSION DIVERTICULUM OF THE ESOPHAGUS*

H. D. Nagel, B.S., M.D.
Waconia, Minnesota

Pulsion diverticulæ of the esophagus are still of sufficient importance to warrant their reporting and inclusion in the literature.

The first reported successful operation for this condition which I was able to find in searching through the literature was that performed in 1886 by Wheeler of Dublin. This was a one-stage operation. Because, however, of its attending high mortality rate, this method of operation has been supplemented by the various two-stage operations of Goldman, Halstead, Murphy, C. H. Mayo, and Judd. These consist of a free dissection of the sac at the first operation, and its complete removal later. The chief and important advantage of the two-stage operation is its comparative freedom from lung and mediastinal complications. Glaub and Jackson performed the combination esophagoscopic and surgical method of operation in these cases. Recently C. Kennedy and Phelps reported a case successfully treated in this manner. A more recent case treated by the two-stage method is reported by C. W. Webb. In reviewing the literature I found that the majority of the reported cases were older than the age of my patient.

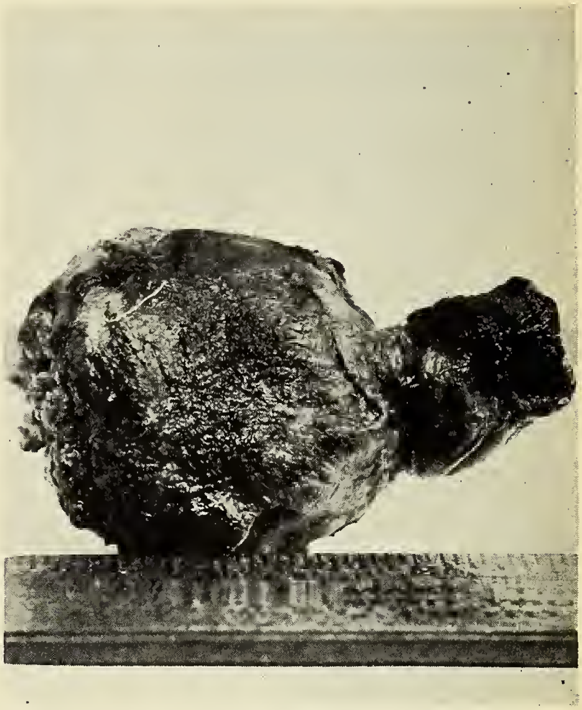

Fig. 1.

I was called to see Mrs. E. Z., a white married woman of forty-seven, who gave the following history. Her present illness began January 18, 1931, at 4 a. m., with a sharp sudden pain in the lower abdomen, more marked over the right side. The pain continued and increased in severity until 11 a. m., when I was called to see her. Her temperature was sub-normal, pulse 88, respiration 18, and there was muscular rigidity of the right rectus muscle, and tenderness over this area.

Her past history recorded a tonsillectomy a few years ago, and an operation for the cure of a rectal fistula in 1918. She had had one child, who was living and well, and had had no miscarriages. The husband was living and well.

Physical examination showed nothing abnormal except the following: A soft mass was present on the right side of the neck suggesting an enlarged thyroid lobe. The lower right quadrant of the abdomen was rigid and tender but there was no distention or mass present. Pelvic examination revealed a tender adnexa, more so on the right, but no palpable mass.

---

*Presented before the Eitel Hospital Staff meeting, Minneapolis, May 22, 1931.

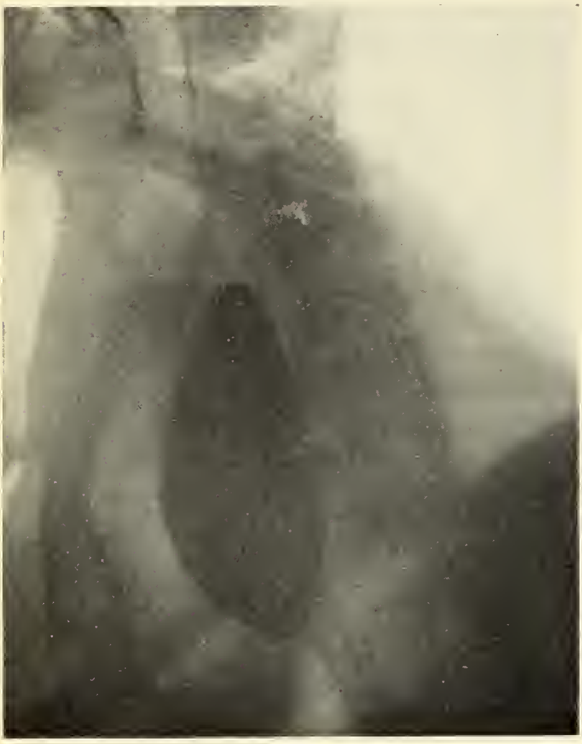

Fig. 2. Lateral view.

The urine was normal, as was the blood picture, except for a leukocyte count of 15,000. A former basal metabolism rate had been a plus 1.

A diagnosis was made of acute appendicitis and the patient was removed to the Eitel Hospital, where I operated upon her for this condition. At the operation, yellow-tinged fluid was found in the vicinity of the appendix and cecum and a larger amount in the pelvic cavity. This fluid was removed by suction. The appendix, which was adherent, swollen, and inflamed, was removed in the usual manner by inversion of the stump and a purse-string method. The gallbladder was found distended, its walls thickened and did not empty well on pressure. The stomach was normal. Three penrose drains were placed in the abdomen, which was closed in the usual layer method. One drain was removed on the fourth and the others on the sixth postoperative day. She made an uneventful recovery, except on the fifteenth day, when an attack of pleurisy set in, which quickly subsided in two days.

During her convalescence the patient noticed, at various times, considerable difficulty in swallowing food, which she attributed to a swelling in her neck. She had the impression that this swelling was a goiter. Due to the fact that she had a basal rate of plus 1 in July, 1929, because the neck varied in size from day to day, and because the swelling was soft and fluctuant, I ordered an X-ray examination. This was performed February 6, 1931, and revealed a diverticulum of the esophagus, 8 cm. long and 9 cm. wide. The lower border of the diverticulum appeared close to the suprasternal notch. On February 7, an esophagoscopy was performed by Dr. Phelps of Minneapolis, a diagnosis of benign diverticulum made, and operation advised.

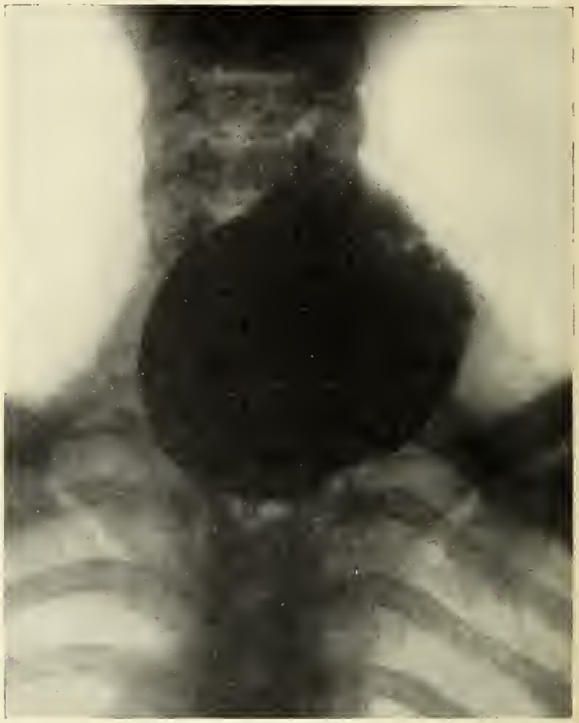

Fig. 3. Anterior-posterior view.

On February 9, 1931, under general anesthesia, the first-stage operation of this diverticulum was performed. An incision was made along the anterior border of the right sterno-cleido-mastoid muscle. The skin, platysma and deep fascia were divided, as was also the deep fascia of the neck. The right lobe of the thyroid was retracted medially and the sterno-cleido-mastoid muscle laterally. The omohyoid muscle was not divided. This incision gave a good exposure of the sac, which was dissected free from its bed and the trachea by blunt and gauze dissection. The neck of the sac was then carefully liberated down to the true esophagus. The sac was then sutured to the edge of the sterno-cleido-mastoid muscle, in an attempt to avoid its possible retraction. Gauze was loosely packed into the former bed of the diverticulum. The skin was closed with skin clips. Vaseline gauze strips were placed along each side of the incision and over the sac.

The following day the patient could swallow liquids without distress. By the fourth day the entire gauze pack was removed. On February 17, or eight days following the first-stage operation, the incision was reopened, and the sac excised at its neck between forceps. Fine chromic mattress sutures were placed behind the forceps on the stump. The forceps were then released and a continuous suture so placed as to control bleeding and bring the edges together. Three more mattress sutures were put in back of the first row. All bleeding being controlled, the incision was closed, chromic sutures being used in the fascia. Skin clips were again used for skin closure. The upper end of the incision was left partially open for drainage. For forty-eight hours no fluids were permitted by mouth, dressings were changed daily and on the fourth day a mucopurulent drainage appeared. Skin clips were removed on the sixth and eighth post-operative days. Drainage continued about the same until the tenth day, when each succeeding day showed a decrease. In four weeks the incision remained perfectly dry. An X-ray film taken five weeks postoperatively is shown. I am indebted to Drs. Robitshek and Herman, of Minneapolis, for their kind assistance.

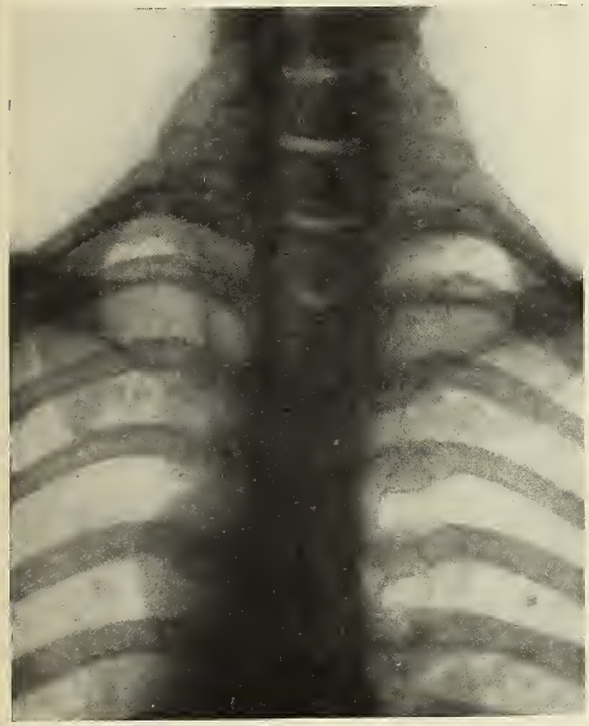

Fig. 4. View taken five weeks later, after operation.

RECTAL MYOMA

Harry F. Bayard, M.D.
Minneapolis

Cases of unusual pathology are reported usually because of the interest generated by a mistaken diagnosis. The case I am reporting here is of rare occurrence and was mistaken for a rectal abscess largely because of the fact that it presented, in addition to the mass felt, an opening in the dentate margin posteriorly and a sinus running up in the direction of the mass, near which a small external opening existed.

Three cases of true rectal myoma are collected and reported by Tuttle in his text, but he reports no case of his own. Gant, in his last edition, does not recall having ever seen a rectal myoma himself. Fibromyomata occur more frequently than the true myoma but even these are uncommon.

The patient was a white male, aged 59, who worked as a fisherman. His chief complaints were, first, a draining sinus in his left buttock, and, secondly, an adenoma of the thyroid. His past history includes only rheumatic fever at twenty-one years. His family history is irrelevant.

The physical examination showed a male weighing 130 pounds and 68 inches in height, with a blood pressure of 130 systolic and 80 diastolic, pulse 74, temperature 98.8°. Teeth were badly worn and pyorrhea (grade II) present. There was a nodular bilateral adenomatous goiter (grade III), without hyperthyroidism; peripheral sclerosis (grade III). A soft, tender mass the size of a hen's egg distended the skin at the left postanal margin. This mass lay outside of the lower left posterior rectal wall. There was a small sinus opening near this mass.

Laboratory findings: Urinalysis—Sp. gr. 1026, acid, albumin 0, sugar 0, micro. negative.

Blood Count—Hemoglobin 70 per cent.

Wassermann—Negative.

A preoperative diagnosis of rectal abscess was made and under sacral anesthesia he was operated upon. The operative procedure was as follows:

A probe was passed into the internal opening and another into the external opening and the incision was made from the internal to the external opening. Then on attempting to palpate the probe through the internal opening a larger cystic mass about 8 cm. long and 5 cm. in diameter was found. This was easily removed by blunt dissection with the finger. It apparently communicated with the same internal opening as the fistula. It contained some fluid about the consistency of water and apparently some mucus but no hair. It closely resembled a post-anal or post-rectal dermoid which had become infected. The cavity thus formed was irrigated with mercurochrome and the distal margin closed except for a small area one cm. long through which a rubber drain was inserted. The mass contained several large cavities and apparently some of the wall was cystic. The fluid had a rather peculiar odor, smelling somewhat like amniotic fluid.

Pathological report: Rectal myoma.

Postoperative notes: The wound filled in by granulation and left the anal canal flexible and competent.

420 Medical Arts Building.

PRESIDENT'S LETTER

I BEGAN my term of office as President of the Minnesota State Medical Association, with a solemn sense of the responsibility and no small sense of apprehension.

Now I am about to close it and in this salute and farewell I am happy to extend most earnest thanks to my fellow officers in this Association, its councilors and committees for their support and assistance, this year. Their coöperation has made my task a pleasure as well as a very distinguished honor.

Our association progresses steadily towards a unity and cohesion that is almost unexampled, I believe, in state bodies of other kinds. It is a power and a factor to be reckoned with on the outside in all fields that legitimately concern it. It is an equally important factor in the maintenance of scientific standards and public conscience among its own members.

These are proud things to say of any organization and I say them with due humility since my part in bringing them about has been infinitesimal in comparison with the general contribution.

The times are critical for the profession of medicine in the United States. We stand, now, where we can see just beyond us—at one turn of the road—the possibility of a system of state medical practice in America comparable to those in effect in the majority of European countries. The path leading to socialization or a paternalistic bureaucracy for the care of the sick seems to many wise men outside of the medical profession, as well as to the majority of physicians themselves, to be an alien by-road unsuited to American institutions and habits of mind. We must not forget however that strain, the presence of economic hysteria, makes it easy to mistake the road.

It is our responsibility to stand guard—if I may continue my figure—at dangerous crossroads; if social medicine is indeed the proper destination for American medicine, then we must point the way. If it is not, then we must direct the private practice of medicine into a wise and effective readjustment of our methods in relation to preventive medicine, adequate distribution of medical care at all income levels and proper medical care for the indigent.

In this connection there is one thing I would particularly urge upon our own membership. That is, in fact, a thorough reading each month of our own medical journal.

The social and economic aspects of medical practice in Minnesota will be discussed at length in the columns of Minnesota Medicine this next year—and by men qualified above the average to deal with them. We cannot do better to prepare ourselves for crises ahead than to follow closely the letters of our new president from month to month; the page forums of our Committee on Public Health Education; the reports of our Committee on Medical Economics and of the Women's Auxiliary. In my opinion it is the individual responsibility of every member of the association to know just exactly what are the public policies of his organization and where they will lead him.

In the end, public welfare as well as the fate of American medicine rests upon the balance and information and social conscience of that already heavily burdened social functionary, the family physician.

L. Sogge

President,
Minnesota State Medical Association.

STATE MEDICINE FOR 4,000,000 VETERANS

Following the World War medical specialists were employed on a part time salary basis under the United States Public Health Service to care for disabilities of veterans resulting from service. It was not long before the Veteran's Bureau operated hospitals of its own and used the services of full time physicians in the employ of the Bureau except for certain consultants. It is a question whether the change in policy furnished the veterans with better medical service as a whole.

In 1924 the scope of disabilities cared for by the Veterans' Bureau was extended to include certain specified disabilities irrespective of their service origin. The next step was to provide in 1926 free hospital care for all veterans *without regard to the nature or origin of their disabilities.* This provision was protested by our national medical organization and various state medical organizations, including our own, as un-American, and physicians were not alone in their objections.

Following this extension of service in 1926 the percentage of non-service disabilities cared for in the veterans' hospitals has increased until in 1930 they comprised a majority of the patients cared for in the 33,128 beds now in existence. According to Dr. Shoulders, the medical council of the Veterans Bureau estimates that a maximum of 129,859 beds will be needed. This means the continuation of an extensive building program during the next few years to provide about 100,000 additional beds.

To quote from a comprehensive article on the subject by Dr. H. H. Shoulders of Nashville which appeared in the A. M. A. Bulletin for October:

> "The average cost of constructing veterans' hospitals is approximately $3,500 per bed. The average cost of the professional staff is $151.56 per year per bed. The cost of maintaining these hospitals in 1930 was $4.42 per bed per day, or $1,613.30 per year per bed. The cost of completing the construction program alone would amount to over $360,000,000. The cost of the professional staff would amount to over $19,000,000 per year, when completed. The cost of maintenance, when completed, would be about $200,000,000 per year. These are not all. The cost of equipment and the cost of transportation of veterans to and from the hospitals cannot be even approximately estimated."

The figures were obtained from the Veterans' Bureau and the estimate of the enormous cost of this hospital building and maintenance program is alarming to taxpayers in general. This cost will be in addition to present appropriations. Private hospitals for the most part erected and operated through generous private contributions and at present about half filled will feel the effect of newly constructed government hospitals, and many will doubtless have to close their doors. More and more veterans will be taken out of the field of private medical practice.

Those who have observed the operation of the present plan of providing hospital benefits to veterans know that the hospital benefits are not and cannot be evenly distributed. Only a very few veterans can live as near a veterans' hospital as a private one. In case of an accident or acute illness requiring prompt surgery the proximity of hospital and surgeon is frequently vital. In certain parts of the less densely populated portions of the country the veteran is hundreds of miles from the nearest government hospital. What is the result? Vital time is lost in reaching the hospital, the long trip is deleterious to eventual recovery, and the patient is better off if he employs the local hospital and physician and pays his expenses himself. Transportation to the nearest government hospital is incidentally a big item of expense to the government and eventually to the taxpayer.

Take a concrete example. A veteran develops a pain in the abdomen. If he lives near enough to a veterans' hospital he seeks relief. Hospitalization is not deemed advisable. By evening the pain becomes unbearable; a private physician is called; the symptoms of acute appendicitis are full blown and immediate operation in a private hospital becomes necessary. Or take an extreme example of a veteran requiring a tonsillectomy. He is advised of the necessity by his private physician. He chooses to have the operation done at government expense. Transportation is provided after more or less delay to the nearest government examiner, who may be miles away. The advisability of operation is determined. Transportation is furnished to the nearest veterans' hospital, perhaps a day's journey distant. The veteran is detained in the hospital where he can be under supervision until fully recovered and given transportation home. The veteran loses a month in time instead of three days and the performance has cost the government three or four hundred dollars.

Numerous similar instances could be cited.

What remedy is there for the situation?

There is a remedy in the proposition known as the "Shoulders resolution" submitted to the House of Delegates of the A. M. A. at its last session. Instead of continuing the present hospital building plan the proposal in a nutshell provides that each veteran be allowed hospital and disability benefits in case of sickness, which will enable him to select his own local hospital and physician. The case is checked by a representative of the Bureau as at present in insurance cases. This would be to the advantage of the veteran, an economy to the government, a life saver for many private hospitals, and would preserve that fundamental relation between patient and physician which permits the selection of the medical advisor. It is not surprising that in numerous instances where the plan has been explained to groups of veterans it has met hearty approval.

THE STATE ASSOCIATION—WHAT IT HAS DONE AND IS DOING

It is customary for business firms to take stock once a year to get a clear idea of their profit and loss. Perhaps many of our members who faithfully pay dues annually into the treasury of the State Association wonder just what becomes of their money and would be interested in having a summary of the work done through their dollars.

Consider first the two boards whose work is most effective because of the efforts of the Association. I refer to the State Board of Medical Examiners and the Basic Science Board. What have they done for the medical men of Minnesota?

From 1925 to 1930, 1,585 poorly qualified physicians were graduated in the United States. This figure is taken from the report of the Council of Medical Education and Hospitals in the Journal of the American Medical Association of April 25, 1931. Their table shows that not one of the 1,585 poorly qualified physicians is located in Minnesota.

From 1924 to 1927 inclusive, before the creation of the Basic Science Board, there were licensed annually an average of 195.5 physicians, 11 osteopaths, and 46.5 chiropractors. From 1928 to 1931 inclusive, following the passage of the Basic Science Law, the yearly average was 192.25 physicians, 5.75 osteopaths, and one chiropractor.

The figures for licensed masseurs show that 215 were licensed in 1929, 201 in 1930, and 189 in 1931. As you all know, before the new Masseur's law placing their licensing in the hands of the State Board of Medical Examiners was passed, there were many quacks practicing medicine under a masseur's license. We never did have any quarrel with legitimate masseurs.

Prior to 1928, there were so few convictions for infractions of the medical practice act as to be practically negligible. Since 1928 the State Board of Examiners has had money derived from registration fees with which to work. In the period from 1928 to date, 196 infringement cases were investigated. Fifty-one were court cases. Forty resulted in conviction and one is still pending. The legal expense has been practically $21,000.00.

We might classify the educational work of the State Association under three headings: (1) for ourselves; (2) for the public; (3) other work to help smooth over the rough places in Medicine.

Under educational work for ourselves, we have the yearly scientific meetings, the extension courses, and MINNESOTA MEDICINE, which ranks high among the journals of its type in the United States. The Consultation Bureau reported some 110 cases in the Journal in 1930. Mention might be made of the Historical Committee, which is about ready to print its first volume.

The educational work for the public is only a few years old. Radio talks for the past three years appear to have been well received by the public. The news service reaches 300 newspapers. Eleven public health meetings were held throughout the state in 1930. We coöperated in the campaign for diphtheria prevention. *Hygeia* and *Everybody's Health* were sent to every member of the Legislature.

This matter of public education may be more or less intangible, as far as results are concerned, but my belief is that it is one of the well worthwhile things that we do and cannot fail to create a more intelligent viewpoint of the medical profession on the part of the public. We are particularly fortunate in this matter of public contact in the fact that our own secretary also represents the largest lay organization in the state, whose function is Public Health work.

We now come to Committee work to help smooth over the rough places.

The Contract Practice committee has been dropped but its successor is known as the committee on Industrial Practice and, under the chairmanship of Dr. Frank Burch, has already considered many matters concerning the relationship of the individual to industrial medicine. Incidentally, Dr. Burch tells us that the present State Industrial Commission is both approachable and coöperative.

We shall not do more than mention the committees on Medico-Legal Affairs, University Relations, the one to investigate the schools for Laboratory Technicians, and that on State Health Relations. They are all doing valuable work.

We now come to the committee which has spent a lot of money but has put us in a very prominent place on the medical map of the United States. We shall mention only a few high spots of the work of the Legislative Committee. The statute of limitations limiting the time in which a malpractice suit may be brought to a two year instead of the former six year period, saves us annually, in malpractice insurance, much more than our annual dues of $15.00 to the State Association. This is beautifully shown in a recent bulletin from Dr. Meyerding's office in which the North Dakota rates, where the six year law prevails, are listed from $50.00 up—for the same protection which costs us $21.00.

The Basic Science Law and the modification of the Medical Practice Act have eliminated from Minnesota many poorly qualified medical men and at least forty-five new chiropractors per year and has helped greatly in meeting some of the criticism of some of our own members "that we have no right to pose as nickel plated angels when we harbor crooks and abortionists amongst our own membership."

The continuation of the service of furnishing Wassermann tests to physicians throughout the state was the result of the efforts of this committee.

We are still able to render our own bills in industrial work instead of accepting a fee schedule of the Industrial Commission.

Also, there have been defeated in the past four or five sessions of the Legislature, very many pernicious measures which, if passed, would have menaced scientific medicine and have broken down all bars which, at present, serve to protect the citizens of Minnesota from charlatans, quacks, and frauds.

F. J. S.

A FORUM OF THE
COMMITTEE ON PUBLIC HEALTH EDUCATION

WHERE THE DOCTOR IS PUBLIC HEALTH WORKER

One of the most important reports on record of a successful coöperation between a County Medical Society and a city health department appeared recently under the title "The Physician as Health Worker" by L. O. Geib and Henry F. Vaughan, both of Detroit, in a recent issue of the Journal of the American Medical Association.

This report is now available as a reprint which might serve as a model for any public health program in any city. In this case it involved a two year diphtheria immunization campaign carried on by the Wayne County Medical Society of Detroit and the Detroit City Department of Health.

Following the launching of this joint plan no further free clinics for administration of diphtheria protection were held anywhere in Detroit. All immunizations were given at a fixed rate between certain fixed hours in the offices of private physicians. The results up to June 1, 1930, were that a very high percentage of children have already been immunized. The actual figures are 80 per cent of all school children and 70 per cent of pre-school children, who have received protection.

Below are some significant extracts from this reprint, copies of which are available from the Wayne County Medical Society. It is well worth the time of anyone interested in public health programs from the standpoint of the private physician, to read the entire reprint:

"In Detroit, as elsewhere" this Detroit report says, "the Health Department has maintained public health clinics over a period of years, with the purpose of teaching pre-natal care to the expectant mother, furnishing instruction to promote infant welfare and preschool and school hygiene, supplying information to those who have been exposed to such communicable diseases as tuberculosis and the venereal diseases, and providing prophylaxis against smallpox and diphtheria. We believe that such clinics have an educational value and are needed during a period of demonstration. Beyond this, there is no justification for their existence except to take care of that small fraction of the population which is always indigent or nearly indigent. Preventive medicine can best be administered through the agency of a medical profession which has been thoroughly enlightened with regard to the practice of disease prevention, a profession which can become keenly alert to its responsibility and ably prepared to play its part in the conservation of the public health and welfare. Any health department which does not organize itself to make available through the office of the family physician the facilities now recognized as available to the modern health department is missing its opportunity. In Detroit, 1,100 physicians became actively interested in preventive medicine. The value of this addition to the roster of public health workers can easily be appreciated. Fundamentally, the problem is one of preparing the public for the service which may be rendered by the physician and at the same time preparing the physician to give the type of service to which the public is entitled."

The factors that have contributed most to the success of this program, as cited in this reprint, have been:

"First, continuous contact between the health department and the public health committee of the medical society, which has met weekly; second, postgraduate medical conferences in communicable diseases, which have been held weekly during the winter months; third, the employment of medical coördinators, who have visited in their office those physicians who never or seldom attend medical meetings of any character; fourth, the inauguration of a program of popular health instruction maintained by the health department, and, fifth, a system of home visitation and instruction of parents by public health nurses."

Charges jointly agreed upon between the Medical Society and the health department were one dollar for each dose of toxin-antitoxin or toxoid in all cases where, in the physician's judgment, the parent was able to pay for the service. The charge for the Schick test and reading of results was likewise one dollar, making a total charge of four dollars for the service. There was nothing in the plan to hinder the physician from charging his usual office fee if the patient appeared at any hour other than that specified in the agreement. It was further agreed that, when in the physicians' judgment the parent was unable or unwilling to pay, the health department should reimburse the physician at the rate of 50 cents for each treatment and one dollar for the Schick test, making a total of $2.50 for the complete service to each child.

OF GENERAL INTEREST

Dr. Ralph L. Parsons is located at Monterey, Minnesota, in general practice.

Dr. G. A. Hedberg of Canby, Minnesota, is house physician at Nopeming Sanatorium, Nopeming, Minnesota.

Dr. Morris Greenberg, a graduate last year at the University, is now in general practice at Wilton, North Dakota.

Dr. Meredith Hesdoffer has recently been appointed member of the staff of the Students' Health Service at the University of Minnesota.

Dr. Gordon E. Strate, St. Paul, following a residence appointment in the Eye, Ear, Nose and Throat department at the Ancker Hospital, has been studying in Vienna. He returned in November.

Dr. Brand O. Leopard has moved from St. Cloud, Minnesota, to Albert Lea, Minnesota, where he has opened offices in the Freeborn County National Bank Building.

At the annual meeting of the Central Neuropsychiatric Association, which was held in Buffalo, October 16 and 17, 1931, Dr. H. W. Woltman of Rochester was elected secretary-treasurer.

The marriage of Miss Marion Elizabeth Ashworth to Dr. E. J. Borgeson, both of Saint Paul, was solemnized Saturday evening, October 10, 1931. Dr. and Mrs. Borgeson, following a trip east, are now at home in Saint Paul.

Dr. S. M. Kirkwood, and family, of Baker, Montana, were recent visitors in Saint Paul, Minn., where Dr. Kirkwood practiced for nearly twenty-five years. Dr. Kirkwood with his wife and son stopped en route to Massachusetts, where they will make their home.

Dr. Carel C. Koch, Minneapolis, has been appointed as a member of National Advisory Commission on Vision for Motor Drivers' which was organized to cooperate with the national street and highway safety conferences inaugurated by President Hoover when he was secretary of commerce.

Physicians wishing to take part in the Scientific Exhibit of the annual meeting of the American Medical Association to be held at New Orleans next May should send in their applications to Thomas G. Hull, Director of the Scientific Exhibit, by January 20, 1932. Application blanks may be secured from the A. M. A. headquarters.

Appointment of Dr. F. E. Harrington, commissioner of public health, Minneapolis, as a member of the advisory board of the Health Research Bureau in the Women's Apparel Industry has been announced through the New York office of the organization. The bureau was formed to encourage healthful styles in women's apparel, according to Jerome Samuels, secretary.

Work on the remodeling of the E. J. Jones residence in Morris, Minnesota, into a hospital is under way. The project was established by a group of doctors and business men of Stevens County. Those at the head of the movement are Dr. E. T. Fitzgerald and Dr. J. F. Cumming, Morris, and Dr. M. L. Ransom, Hancock. When completed the hospital will accommodate eighteen patients.

Dr. L. A. Sukeforth of Duluth, public health director of that city for eight years, has retired from office. No successor has as yet been named. A plan for reorganizing the department, which will call for a full time specially trained supervisor as the department head, is being worked out by a committee of the St. Louis County Medical Society. Dr. A. J. McLaughlin, medical director of Chicago, has been named by the Bureau of Public Health, Washington, D. C., to assist the Duluth committee in reorganizing the department.

Dr. William J. Mayo of Rochester, Minn., was named president-elect of the International Assembly of the Interstate Postgraduate Medical Association at the meeting held in Milwaukee the latter part of October.

Dr. Arthur Dean Bevan, of Rush Medical College, Chicago, became president for the ensuing year. Other officers confirmed were: Dr. Charles H. Mayo, Rochester, and Dr. Edward Archibald, Montreal, heads of assembly clinics; Dr. William B. Peck, Freeport, Ill., managing director; Dr. Henry G. Langworthy, Dubuque, treasurer and director of the Foundation Fund; and Dr. George W. Crile, Cleveland, chairman of the program committee.

The nominating committee consists of Dr. E. M. Eberts, Montreal, chairman; Dr. B. J. Lee, New York; Dr. E. Starr Judd, Rochester, Minn., and Dr. Henry Christian, Boston, Mass.

Medical examinations for the unemployed are being utilized in Minnesota in an attempt to discover whether men and women who are frequently or generally out of work are suffering from physical disabilities that prevent their success as workers. This undertaking is part of the Minnesota Employment Stabilization Research Institute's work of making an intensive study of basic conditions of unemployment in Minneapolis, St. Paul, and Duluth. Mental tests and tests for vocational interests, trade skill proficiences, and personality traits are being given in addition to the medical examinations to four thousand unemployed individuals who have registered at the Institute headquarters at the University of Minnesota. Bulletins reporting the findings of this organization, which will also make a study of industrial conditions and public employment offices in the three cities, will be published by the University of Minnesota Press at intervals during the next two years.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

"NATUROPATH" SENTENCED TO FORTY DAYS IN COUNTY JAIL

State of Minnesota *vs.* Dana L. Hewett.

On October 16, 1931, Dana L. Hewett was arrested at Anoka, Minnesota, charged with practicing healing without a Basic Science certificate. Complaint was filed by Mr. Brist on behalf of the State Board of Medical Examiners. The defendant is a man about fifty years of age and maintained his office at 1807 First Avenue South, Anoka. The defendant was holding himself out to the public as follows:

> Remove the cause and nature will complete the work. Functional and organic diseases successfully treated.
>
> D. L. HEWETT
> Naturopath
>
> 1807 1st Ave. S., Anoka. Phone 544 J.
> Hours 9 A. M. to 5 P. M.
> Evenings and Sundays by appointment.

Following his arrest, Hewett waived his preliminary hearing and was held to the District Court under bond of $500. On October 21, Hewett entered a plea of guilty and was sentenced by the Honorable Arthur E. Giddings, Judge of the District Court, to a term of forty days in the county jail. The sentence was suspended and the defendant placed on probation on condition that he shall refrain from pacticing healing in the State of Minnesota. The State was represented by Leeds H. Cutter, County Attorney, and the defendant was represented by W. A. Blanchard, former State Senator from Anoka.

ST. PAUL MASSEUSE AND FORMER NATUROPATH SURRENDERS MASSAGE LICENSE

State of Minnesota *vs.* Schultz.

Mrs. Pauline L. Schultz, 633 Hamm Bldg., St. Paul, surrendered her massage license to the State Board of Medical Examiners on October 26, 1931. Mrs. Schultz, who claims to be a Naturopath, has been under indictment for manslaughter since last spring following the death of a St. Paul girl after an alleged abortion.

Mrs. Schultz has maintained offices in the Hamm Building for several years, where she has practiced under a massage license. The County Attorney's office, through no fault of its own, was unable to produce certain essential evidence in this case and it was therefore deemed advisable not to attempt a trial of the indictment. However, before the indictment was nolled on October 26, 1931, Mrs. Schultz advised the Board in writing that she was surrendering her massage license and closing her office. The office is to be closed on or before December 1, 1931.

CHIROPRACTOR GIVEN SIX MONTHS JAIL SENTENCE

State of Minn. vs. George F. Sjoden.

On November 12, George F. Sjoden, licensed chiropractor with an office at Kensington, Minnesota, was sentenced to six months at hard labor in the County Jail of Douglas County by the Honorable John A. Roeser, Judge of the District Court, for practicing medicine without a license. The defendant formerly practiced at Princeton and Motley, Minnesota. He has been prescribing medicine and attempting to remove tonsils. Complaint was filed against Dr. Sjoden by Mr. Brist, representing the State Board of Medical Examiners, before Sherman Costello, Justice of the Peace at Alexandria, Minnesota.

After having the Medical Practice Act and the Chiropractic Law very carefully explained to him, Judge Roeser suspended the sentence on condition that he pay the costs of the prosecution, that he refrain from practicing medicine in the future and that he keep the peace and be of good behavior. Dr. Sjoden, being licensed only under the Chiropractic Law of this State, has no authority whatever to prescribe medicine or remove tonsils.

Very splendid coöperation was received in the prosecution of this case from Mr. C. F. Hanson, County Attorney of Douglas County, and Sheriff Bennie Urness.

CHRISTMAS SEAL SALE

The annual Christmas Seal Sale for the purpose of raising funds to fight tuberculosis takes the stage this month.

It is significant of the healthy condition in which this Christmas Seal movement finds itself on the occasion of its 25th anniversary that it is not resting comfortably in old grooves, holding abandoned batte fronts.

As the National Tuberculosis Association, the Minnesota Public Health Association and all of their affiliated bodies in every state begin the 1931 campaign for funds, medical men will gladly acknowledge that they are in the vanguard in the education of the public to the newest epidemiological methods of control of tuberculosis and also in their national program of research into the nature of the disease.

This is the appeal which this movement makes to physicians, an appeal which sets it apart from many other benevolent undertakings. The National Tuberculosis Association is headed and managed by physicians and the Minnesota Public Health Association, its representative in Minnesota, is an active partner of the State Medical Association in the promotion of legitimate general health and anti-tuberculosis propaganda.

In that sense, the cause of the Christmas Seal in Minnesota is especially the cause of organized medicine and will, no doubt, receive the same staunch support this year that it has always received.

No one can doubt that reduced circumstances, meaning reduced scales of living, also mean reduced resistance to disease of all kinds, particularly tuberculosis. Among many emotional appeals for help for the unfortunate, this year, the sober appeal for more funds to fight tuberculosis will have a vivid reality in the minds of medical men. In most localities of the state, the Minnesota Public Health Association, with the authorization of the state and county medical societies and with their coöperation, has led in the important work of introducing and demonstrating the routine Mantoux testing of children. A threatened increase in the incidence of the disease will mean greater need than ever for this type of program which points the way toward discovery of infection at a time when it is possible to protect the child from active pulmonary disease.

Some interesting figures on comparative rates of tuberculosis infection in the towns and in the rural sections of Minnesota have come to light during the testing of the last year carried on both directly by the Christmas Seal organizations and indirectly in coöperation with the sanatorium districts of the state. In all, 30,000 tests have been made, mostly among other than known contact groups, with percentages of positive reactors running as low as six per cent in Ottertail County and 12.6 per cent in the city of Owatonna, on the one hand, and 25 per cent among city grade school children and 34.25 per cent among high school seniors tested as a group in Saint Paul.

Throughout the state these testing programs have discovered in all 70 unsuspected cases of open, active tuberculosis. The childhood type cases numbered 456. The number of cases discovered does not, of course, represent the whole value of the undertaking. To the home of each positive reactor went a warning of the significance of the reaction and a suggestion that the child see his physician, not only for a physical checkup but for help in discovering the source of the infection. This is practical education in tuberculosis control, a program in which the Christmas Seal organization will have the continued approval and coöperation of the medical profession.

OBITUARY

Daniel D. Murray

1859-1931

Dr. D. D. Murray, for forty years a practicing physician at Duluth, died November 6, 1931. Dr. Murray at one time was City Health Commissioner and for several years was medical examiner for the State Athletic Commission of Minnesota.

Frederick Barrett

1875-1931

Dr. Frederick Barrett, mayor of Gilbert for seventeen years, died suddenly at his home November 4, 1931.

Dr. Barrett, who was fifty-six years old, went to Tower in 1888 and also had lived at Eveleth before coming to Gilbert. He is survived by one son, John, a student at the University of Minnesota; a brother and two sisters.

Frederick J. Mitchell

1879-1931

Dr. Frederick J. Mitchell, Saint Paul, was accidentally shot while hunting near Albert Lea on October 8, 1931. Born at Rockland Center, Wisconsin, July 17, 1879, he studied medicine at Hahnemann Medical School, Chicago, and received his degree from Northwestern Medical School in 1909.

Dr. Mitchell practiced at Euclid, Minnesota, from 1903 to 1908, and had practiced in the Payne Avenue district of Saint Paul for twenty-two years.

Walter Henry Robilliard

1861-1931

Dr. W. H. Robilliard, seventy years old, died Sunday, November 1, 1931, at his home in Faribault, Minnesota. For thirty-five years a prominent practicing physician in Faribault, he also was an outstanding leader in civic and fraternal life.

Dr. Robilliard was a member of the Rice County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Surviving are his widow, two sons, Dr. Charles and Harold S.; a daughter, Mrs. Lyle Day of Minot, N. D.; and a sister, Mrs. H. S. Cleveland, of Minneapolis.

Reuben Nathaniel Palmer

1893-1931

Dr. Reuben N. Palmer, Kenyon, Minnesota, died Tuesday evening, November 3, 1931, as the result of a heart attack. He was thirty-eight years old. A graduate of the University of Minnesota medical school, where he was a member of Phi Beta Pi medical fraternity, he served his interneship at Ancker hospital, St.

Paul. Dr. Palmer began practice at Lanesboro, where he was located for about six years, moving to Kenyon only recently.

He was a member of the American Medical Association, Minnesota State Medical Association, secretary of the Houston and Fillmore County Medical Society, member of the Rice County Medical Society, Masonic lodge of Lanesboro, Kiwanis club, Izaak Walton league and First Futheran church of Kenyon. Dr. Palmer served in the medical corps in the World War.

He is survived by his wife; four brothers, George, Gunnar and Elder of Chisago City and Carl of Lindstrom; and two sisters, Anna and Astrid of Chisago City.

MISCELLANEOUS

THE SUPRACRICOID ADMINISTRATION OF LIPIODOL

Geoffrey Cottam, M.D.
Minneapolis

Each method of introducing lipiodol into the bronchial tree has its merits. In this brief communication, I wish to present the reliability and advantages of the above named route.

The various methods are:

1. Ochsner's cocain anesthetization of the pharyngeal ring with a resultant loss of the swallowing reflex. The patient is instructed to take a mouthful of the oil and tilt the head back. The lipiodol then runs down the trachea.
2. A method used by Pritchard whereby the oil is administered through a cannula placed between the vocal cords after laryngeal cocainization.
3. A type used in Graham's Clinic utilizes a glass syringe and a long needle. The tongue is pulled forward as the oil is dropped from the end of the needle on the back of the tongue. The oil overflows into the trachea.
4. The bronchoscopic administration.
5. Lastly, the supracricoid method in which a syringe and an ordinary "hypo" needle are used. The cricothyroid membrane is punctured and the medium injected into the trachea.

The technic of the latter operation is very simple. One half hour before injection, the patient's shoulders are lowered below the level of his hips and he is instructed to cough up all sputum. Introduction of oil on top of sputum may cause patches of bronchopneumonia. Twenty minutes before injection he is given ¾ of a grain of codein sulphate by hypodermic. He is then taken to the X-ray room and set upon a chair. The area over the throat is sponged with alcohol and a syringe full of lipiodol with a hypo needle is heated over a Bunsen flame. The cricoid is palpated and with one quick thrust through the skin and crico-thyroid membrane the needle enters just below the larynx. By pulling back on the plunger, air will enter the syringe if the needle is in the air passage. The patient is then tilted to the side of disease at an angle of 45° and he is instructed not to cough or swallow and to take short deep breaths like the panting of a dog. The oil is then introduced to a point where gurgling in the trachea is noticed. Warning the patient not to cough, the needle is removed and he is placed for an X-ray picture. Ten to 40 c.c. of lipiodol may be necessary.

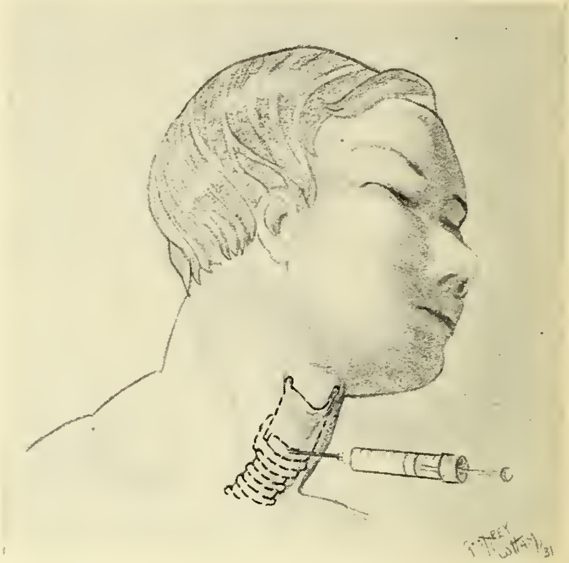

Fig. 1. For clarity the needle has been enlarged. This shows needle entering infra-laryngeal region through crico-thyroid membrane.

Upper lobe injections may be made by placing the patient on a table on the diseased side, with the feet down, at a 45° angle and when gurgling in the trachea is noted the table is inverted with the head down at an angle of 45° for one minute. The film is then taken with the table flat and the patient on his diseased side. The whole procedure takes but fifteen minutes.

The advantage over all the other methods is that it is always successful. Upper lobes may be injected with greater facility than with other methods. More adequate filling of the bronchial tree may be obtained. Patients who have had one of the other methods as well as the supracricoid, prefer the latter,—they do not mind the hypo needle as much as the gagging by the other methods. The only complication in the four years that I have been doing this work was a superficial infection in the neck, which readily yielded to hot wet dressings. The only contraindication is a septic lung (as pneumonia) or very active pulmonary tuberculosis. In low grade activity it may be used. Again, it can be done in much less time than that required by the other methods and there is not the annoyance of gastric disturbance from swallowing the oil.

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

MEDICAL BROADCAST FOR THE MONTH

The Minnesota State Medical Association Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 11:15 o'clock every Wednesday morning over Station WCCO, Minneapolis and Saint Paul (810 kilocycles or 370.2 meters).

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota.

The program for the month of December will be as follows:

December 2—Diagnosis of Intussusception
December 9—Epilepsy Cures
December 16—The Tuberculin Test
December 23—Control of Communicable Diseases
December 30—Attitudes toward Cancer

THE AMERICAN COLLEGE OF PHYSICIANS

The Sixteenth Annual Clinical Session of the American College of Physicians will be held in San Francisco, California, April 4 to 8, 1932. The headquarters in San Francisco will be the Palace Hotel, where the general scientific sessions, registration, and exhibits will be held. Clinics will be conducted in various hospitals and institutions in San Francisco and nearby communities.

Dr. S. Marx White, Minneapolis, President of the College, has in charge the selection of speakers and subjects on the general program, while Dr. William J. Kerr, San Francisco, Professor of Medicine at the University of California Medical School, is the General Chairman of the Session, and is responsible for all local arrangements, in addition to the arrangement of programs and demonstrations. Following the San Francisco Session a post-convention tour will be conducted through Yosemite Valley, Southern California (with two days in Los Angeles), and the Grand Canyon of Arizona.

The attention of the secretaries of various societies is called to the above dates, in the hope that their societies will select non-conflicting dates for their 1932 meetings.

NATIONAL SOCIETY FOR PREVENTION OF BLINDNESS

The annual meeting of the National Society for the Prevention of Blindness will be held on Thursday, November 19, in the Russell Sage Foundation Building, 130 East 22nd Street, New York City, it is announced by Lewis H. Carris, Managing Director.

Dr. William Campbell Posey, of Philadelphia, Pa., a member of the Society's Board of Directors, will speak on "The Evolution of the Cataract Operation." Following this address a motion picture to demonstrate the cataract operation will be presented by Dr. Frank C. Parker, of Norristown, Pa.

Among other topics that will come up for discussion will be: Medical social service in eye hospitals and clinics, preventing eye troubles in babies, sight-saving classes for children with defective vision, trachoma research, prevention of industrial eye injuries, etc. Members and friends of the Society are cordially invited to attend.

MINNESOTA RADIOLOGICAL SOCIETY

A joint meeting of the Minnesota Radiological Society, the Iowa X-ray Club and the Radiological Section of the Wisconsin State Medical Society was held at the Mayo Clinic, Rochester, Minnesota, October 17, 1931. The Societies were honored by the presence of Dr. Charles H. Mayo, who delievered an address of welcome, and Dr. Lewis Gregory Cole of New York, who was the guest speaker. The following program was presented:

1. Round table discussion of gastro-intestinal diseases. Conducted by Dr. Lewis Gregory Cole, New York.
2. "Benign Tumors of the Stomach."
   Dr. Leo G. Rigler, Minneapolis.
   Discussed by Drs. L. G. Cole, J. D. Camp, C. G. Sutherland.
3. "Fractures about the Ankle Joint."
   Dr. M. S. Henderson, Rochester.
   Discussed by Drs. W. H. Ude and G. T. Nordin.
4. "Results of Radiation Therapy in Carcinoma of the Skin."
   Dr. L. G. Ericksen and Dr. K. W. Stenstrom, Minneapolis.
   Discussed by Drs. Gage Clement, Hamilton Montgomery and S. W. Harrington.
5. "Intrathoracic Tumors."
   Dr. S. W. Harrington, Rochester.
   Discussed by Drs. C. H. Mayo and L. G. Rigler.
6. "Tuberculosis in Children."
   Dr. T. A. Burcham, Des Moines.
   Discussed by Drs. E. S. Hewitt, Arnold Anderson, L. G. Rigler.
7. "Bone Changes in Hyperparathyroidism."
   Dr. John D. Camp, Rochester.
   Discussed by Drs. J. deJ. Pemberton and R. M. Wilder.

Following the banquet the principal address of the meeting, "Correlation of the Roentgenologic Appearance with the Pathologic Changes of Gastric Ulcer," was delivered by Dr. Lewis Gregory Cole, New York.

Leo G. Rigler, M.D., *Secretary,*
Minnesota Radiological Society.

IOWA STATE MEDICAL SOCIETY

An invitation has been extended through the Secretary of the Iowa State Medical Society, Dr. Robert L. Parker, to the members of the Minnesota State Medical Association to attend the annual meeting of the Iowa State Medical Society which is to be held at Sioux City on May 4, 5 and 6, 1932.

MINNESOTA SOCIETY OF INTERNAL MEDICINE

At the semi-annual meeting of the Minnesota Society of Internal Medicine the following officers were elected: Henry L. Ulrich, president; H. Z. Giffin, vice president; Moses Barron, secretary-treasurer. The next meeting will be held at Duluth in June, 1932.

SOUTHWESTERN MINNESOTA SOCIETY

The Southwestern Minnesota Medical Society met at Slayton, Minnesota, October 6, 1931, for the semiannual meeting. Dr. W. G. Benjamin, Pipestone, Minn., and Dr. S. A. Slater, Worthington, Minn., lectured on their experiences in visiting medical clinics of Europe.

The following officers were elected for the ensuing year: President, Dr. S. A. Slater; vice president, Dr. J. T. Rose; secretary-treasurer, Dr. E. G. McKeown.

The following censors were re-elected for a period of three years: Dr. A. H. Brown, Pipestone County; Dr. C. O. Wright, Rock County; Dr. J. H. Dudley, Cottonwood County.

E. G. McKeown, M.D.
Secretary.

STEELE COUNTY SOCIETY

At the annual meeting of the Steele County Medical Society held October 13, 1931, the following officers were elected for the ensuing year: President, J. A. McIntyre, Owatonna; vice president, E. W. Senn, Owatonna; secretary-treasurer, D. H. Dewey, Owatonna; censor for three years, J. F. Smersh, Owatonna; delegate to state meeting, A. B. Stewart, Owatonna; alternate, E. J. Nelson, Owatonna.

These officers will assume office at once.

WEST CENTRAL AND KANDIYOHI-SWIFT SOCIETIES

The West Central and Kandiyohi-Swift County Medical Societies held a joint meeting at Morris, Minnesota, October 14, 1931. A banquet was served at the La Grande Hotel. After dinner Dr. Emil Geist of Minneapolis gave a very interesting moving picture lecture on "The Treatment of Fractures."

Officers elected for the following year are: Dr. N. F. Doleman, Tintah, President; Dr. B. Karn, Ortonville, Vice President; Dr. A. L. Lindberg, Wheaton, Secretary-treasurer.

A. L. Lindberg, M.D., *Secretary.*

WASHINGTON COUNTY SOCIETY

The monthly meeting of the Washington County Medical Society held October 13, 1931, was well attended. The outstanding features of the program were lectures by the guest speakers, John C. McKinley, M.D., Professor of Nervous and Mental Diseases at the University of Minnesota, and Wallace Cole, M.D., Saint Paul. The subject was "Infantile Paralysis." Dr. McKinley covered the medical aspect of this disease, its probable cause, early recognition and attempts at prevention and treatment. Dr. Cole took up the prevention and treatment of deformities, illustrating with lantern slides.

The evening was most profitable and enjoyable.

E. Sydney Boleyn, M.D., *Secretary.*

THE MISSISSIPPI VALLEY CONFERENCE ON TUBERCULOSIS

The joint annual meeting of the Mississippi Valley Conference on Tuberculosis and the Mississippi Valley Sanatorium Association which met this year in Saint Paul in September, showed a registration of some five hundred individuals from twelve Mississippi states. The large proportion of those in attendance from outside the medical profession indicates the widening social aspect of the anti-tuberculosis activities of today. Social service, city and county problems, out-patient clinics—all had their share in the program.

WOMEN'S AUXILIARY
Minnesota State Medical Association

President—Mrs. James Blake, Hopkins
Chairman Press and Publicity—Mrs. Glen R. Matchan, Minneapolis
Editor—Mrs. Horatio B. Sweetser, Jr., Minneapolis

MINNESOTA STATE AUXILIARY

Wednesday morning, October 28, the executive board of the Minnesota State Medical Society met with the president, Mrs. James Blake. After the business session, Dr. C. B. Wright gave an interesting talk on "The Conduct of the Veterans' Bureau as It Pertains to Hospitalization and Medical Care." Following the meeting a luncheon was served with Mrs. McGlothlan, national president, as guest of honor.

HENNEPIN COUNTY AUXILIARY

The Woman's Auxiliary to the Hennepin County Medical Society gave a reciprocity tea, October 28. The presidents and members of the county societies throughout the state had been invited and about seventy-five attended. Mrs. Arthur McGlothlan of St. Joseph, Missouri, national president of the Women's Auxiliary to the American Medical Association, was guest of honor. She gave a brief address sketching the work and ideals of the national group.

RAMSEY COUNTY AUXILIARY

The executive board of the Ramsey County Auxiliary entertained at a luncheon, Thursday, October 29, in honor of Mrs. McGlothlan, national president. Other guests were Mrs. James Blake, state president, Mrs. Martin Nordland, president of Hennepin County Auxiliary, and Mrs. Hugh Tunstead, president-elect of Hennepin County. The same evening Mrs. Hesselgrave, past state president, entertained at a dinner in honor of Mrs. McGlothlan. The guests included the executive board of the Ramsey County Medical Auxiliary and the past presidents of the State Auxiliary and Mrs. James Blake, state president.

PROCEEDINGS OF THE MINNESOTA ACADEMY OF MEDICINE

Meeting of October 14, 1931

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, October 14, 1931. After the dinner at 7 p. m., the meeting was called to order at 8:15 p. m. by the President, Dr. J. S. Gilfillan.

There were 45 members and 2 visitors present.

Minutes of the May meeting were read and approved.

Dr. Moses Barron, who was announced to read his Thesis at this meeting, was unable to be present. So arrangements had been made to have

Dr. Max Hoffman, St. Paul, read his Thesis entitled "Observations in the Diagnosis of Gallbladder Disease."

DISCUSSION

Dr. Arnold Schwyzer, St. Paul: I think it would be healthful for most surgeons if their material were gone through by somebody else in an impartial way without the surgeon trying to "have a finger in the pie." From what date to what date were those cases taken?

Dr. Hoffman: From 1926 to 1930.

Dr. Schwyzer: How many deaths?

Dr. Hoffman: One. This patient died two weeks after the operation from pneumonia.

Dr. Schwyzer: One point is that the diagnosis cannot always be made absolutely even with the Graham-Cole test; there will away be a few cases where we don't know whether we do the right thing in taking out the gallbladder or leaving it in. We also will have a few cases that will not turn out right. In the X-ray examination, I know we sometimes differed; Dr. Hoffman had his ideas about the case, and I had mine, but I must admit his percentage of correct diagnoses was larger than mine.

He mentioned among the symptoms—and I think that is one of the most important for the surgeon to go by—that if the pain is in the first part of the night the patient may have duodenal ulcer, but if the pain comes after 2 o'clock in the morning it is practically always a gallbladder case. About 20 years ago Rutherford Morrison of England made this statement, and I do not think it ever failed me.

Dr. A. T. Mann, Minneapolis: This has been a very well worked out paper and well given; it deserves more discussion. In my experience a great many of these cases do have stomach symptoms which are often mistaken for ulcer of the stomach or duodenum and some other things, and I have been very much interested in trying to unweave some of the characteristics of these symptoms. It seems to me that with the ulcer symptoms the symptoms are apt to be worse in the spring and fall, and when similar symptoms come from the gallbladder it is not at those times but they are more apt to come in the winter and summer. So the point of incidence is different.

Then when we come to the foods which make the symptoms worse, for ulcer we have a whole list of things which are well-known—sugars, acids and fatty foods. It seems to me that usually when you have an ulcer and there is a type of food which makes it worse there is a whole list of the same type of foods that make it worse; but if it is the gallbladder there may be only one, perhaps two, which make it worse, but not the whole list. I have had cases where it was apple sauce which made the symptoms worse, and the patient could eat other things all right; or in other cases it may be something else. Usually if you go into these histories carefully, you can find there are one or two foods which tend to upset the patient and make him worse, whereas if the condition were ulcer you could expect a long list of that class of foods to make it worse.

There was a large incidence of stones in these cases. I believe there are a good many without stones that have so much disease in the gallbladder that they have very definite symptoms and they get relief after operation. Now, how are we going to get at those cases? You do not see stones in the X-ray; you may see change of function with the dye tests, and you will have as a rule the digestive disturbances. But, as a rule, if the case approaches a situation where surgical removal should be done, we have usually a pretty definite point of tenderness in the gallbladder region just as we do in the appendix region in appendicitis.

In my own mind, I formulate it something like this: If we have symptoms that might be reflex symptoms from the stomach and we have a patient who has disability from that so that he cannot do his work and, in addition to that, we do get the tenderness over the gallbladder, those cases I think are surgical.

Dr. C. B. Wright, Minneapolis: I would like to express my appreciation of this paper. The careful analysis of so large a series of cases operated on by a surgeon whose conservatism is proven by the large number of cases which showed advanced pathology, is of real clinical value.

In regard to the question of gastric acidity in gallbladder disease raised by Dr. Hoffman, it is true that there are different opinions expressed in the literature. I believe, however, it is fairly generally conceded that in old gallbladder cases showing advanced pathology the acids are lower and frequently absent.

Old gallbladder cases constituted quite a large percentage of some 175 cases showing no free HCl in the stomach with the fractional meal, a third of the cases failing to respond to histamine. I believe there is some connection between functionless gallbladders and achlorhydria. I have observed cases in which acid was present before the removal of the gallbladder and disappeared afterwards. This is not an unusual finding.

Gagschat showed experimentally on dogs that removal of the gallbladder produced entire absence of gastric acidity which persisted at least one year.

One must remember the fact, however, that approximately 30 per cent of people over 60 will show absence of free HCl with the ordinary test meal and in gallbladder disease we are dealing with a fairly old group as a rule.

Dr. Hoffman also speaks of one case with right lower quadrant pain. I would like to know how he explains a pain in this region due to the gallbladder.

Dr. A. W. Ide, St. Paul: I would like to ask Dr. Hoffman whether or not any symptoms were observed from the use of this dye? It has seemed to us that it is better to delay operation in these cases until there is time for the dye to be eliminated. We have observed that cases operated upon soon after the dye was given had a rather stormy time for a while after the operation.

Dr. A. A. Zierold, Minneapolis: I wish to congratulate Dr. Hoffman on his paper. Whenever the subject of gallbladder diagnosis and treatment is offered, internists and surgeons alike feel free to discuss it at length; possibly because there is so little exact knowledge available. From Dr. Hoffman's paper it seems that a question may be raised as to the identity of gallbladder disease. We may identify as suffering from gallbladder disease (1) that patient experiencing qualitative food distress, abdominal discomfort, belching, etc.; (2) that patient whose gallbladder fails to conform to the limits of the Graham-Cole test; (3) that patient whose gallbladder on microscopic examination is abnormal. As these findings are not commonly present in all cases it would seem reasonable that diagnosis be limited and directed to but one of the three groups. Dr. Wright has mentioned a point which has been of particular interest to me because of some observations which we have been making at the Minneapolis General Hospital. It has been noted for some time that abnormal gallbladders, particularly those with obstruction of the cystic duct, are frequently accompanied by functional achlorhydria. For the past year or more we have been doing routine fractional determinations of the stomach content on all gallbladder cases coming to operation. We have found, as was to be expected, that the majority of these cases showed free hydrochloric acid only upon the exhibition of histamine. Following operation, further study of the gastric content was made at stated intervals, and with few exceptions the functional achlorhydria disappeared with removal of the gallbladder. If, on further observation, these findings proved constant, it would appear reasonable to believe that some of the symptoms attributed to gallbladder disease *per se* are really disturbances of secretion and, consequently, motility of the stomach. It might also be reasonable to assume that routine examination of the stomach content might aid in determining the prognosis of gallbladder operations.

Dr. H. B. Sweetser, Minneapolis: In connection with the complications which occur in gallbladder disease, I would like to mention a case which recently came under my care:

Nearly a year ago I was called by a physician about midnight to see a patient, who had been, earlier in the evening, suddenly stricken with extreme pain in the epigastrium and was in shock. At operation was found an acutely inflamed gallbladder full of stones, but also an enlarged and hard nodular pancreas, together with many areas of fat necrosis in the large omentum. We removed the gallbladder, and the patient recovered and left the hospital, but did not do well and continued to complain. About two months ago the patient again came under observation and now, on examination, presented a large tumor mass in the epigastrium, which at operation proved to be a cyst of the pancreas. Because of the relationship of pancreatitis to inflammation of the gallbladder and its dependence thereon, I have wondered if, at our first operation, had we drained the gallbladder instead of removing it, the pancreatitis might have subsided without such cyst formation.

Dr. A. Schwyzer, St. Paul: That lumpy condition of the pancreas we find quite frequently in cholecystitis and I think it usually disappears with a cholecystectomy. I think it is secondary to the infection from the gallbladder. I remember one case that had a regular pyramid formed by the swelling of the pancreas. That was many years ago when we did not take out the gallbladder as a routine in these cases. In that case we took out the stones and drained the gallbladder and the patient was quite well for probably nine months, then began getting worse again. There were no stones this time, and yet this great swelling in the head of the pancreas had formed again. I figured that the patient had a persistent cholecystitis, and so took out the stoneless gallbladder, and the patient has remained well since. That swelling in the head of the pancreas we could feel through the flabby abdominal walls. I think Dr. Sweetser did the right thing in his case.

Dr. A. E. Benjamin, Minneapolis: There are other diseases or complications that present symptoms similar to gallbladder trouble. I have seen individuals with prolapse of the stomach and colon which gave symptoms that resembled gallstones and were so diagnosed, but when they came to the hospital for investigation it was found that a kink existed in the hepatic flexure of the colon. Colitis and pericolitis associated with gallbladder disease may modify the symptoms considerably.

Dr. Hoffman, in closing: I want to take this opportunity to thank the members of the Academy for the privilege of presenting this paper, and especially the members who were kind enough to discuss it.

In answer to Dr. Wright's question, I don't know just why the pains occur in the right lower abdomen. We know there is a frequent association between gallbladder disease and appendicitis, and some of our patients had that combination, but just what the percentage is I do not know. We very frequently see in the cholecystogram that the gallbladder is very low in the pelvis. The difference of opinion regarding stomach acidity in gallbladder cases shown in a number of reports, some indicating hyperchlorhydria and some an achlorhydria; but many of the reports indicate that there is no change or decrease in the acid. I was glad to hear the statement that after the removal of the gallbladder there was a diminution of the free acid because that might account for our three patients who had diarrhea.

Dr. Ide asked about the reaction from the dye. When we first started making the cholecystograms we used the dye in capsules and we had quite a lot of trouble;

the patient would call us up in the night and tell us he was having a great deal of nausea and vomiting. But since we have been using the emulsion and grape juice we have had very little trouble. Occasionally there is diarrhea with nausea and vomiting, but none of the patients get very sick. I don't know what effect it would have on the patients to operate on them soon after taking the dye; usually they are operated on quite a while after taking the emulsion.

Dr. Martin Nordland, Minneapolis, read a paper on "The Relief of Pain in Advanced Tuberculosis of the Larynx by Means of Surgery." This was illustrated with lantern slides.

ABSTRACT

The relief of pain in far-advanced tuberculosis of the larynx is important because, as a result of pain, there is a diminished intake of food and rapid failing of the patient. The author has had the opportunity of bisecting the superior laryngeal nerve five times for this purpose.

Applications of various remedies to the ulcerated surfaces have never been satisfactory.

Injections of alcohol into the superior laryngeal nerve, for the relief of pain, has many disadvantages. Among these are: the varied experience of the operators; the relief of pain is only transient, varying from a few hours to six weeks; repetition is difficult on account of connective tissue formation; the pain of recurrence is often more severe than the original pain; and because there is occasional paralysis of the tongue due to the extension of the alcohol to the hypoglossal nerve.

Bisection of the internal branch of the superior laryngeal nerve is recommended as the surest method of relieving dysphagia, because it is simple, without technical difficulties, has no contraindications and because it partially immobilizes the vocal cords as well as relieves the pain.

The anatomy to be considered is the same as that for ligature of the superior thyroid artery, because the superior laryngeal nerve is so closely related to this artery.

The operation is done after using a few cubic centimeters of two per cent novocain, after the patient has been put in the same position as for thyroidectomy.

After the operation all painful sensation upon swallowing food disappears immediately. When pain persists after the resection of the superior laryngeal nerve, it can be assumed that the ulceration is not confined to the larynx.

The operation has a definite symptomatic value and may have a curative possibility.

The operation is suitable for other painful inflammatory processes in the larynx.

DISCUSSIONS

Dr. F. L. Jennings, Oak Terrace (by invitation): Tuberculosis of the larynx is a secondary condition and usually occurs with advanced tuberculosis of the lungs. The marked soreness and painful swallowing that Dr. Nordland has spoken of is the result usually of extensive disease in the larynx. I have here two models which show extensive tuberculosis of the larynx and it is in lesions similar to these that patients suffer so much.

I was familiar with the previous work of Dr. Nordland in which he had shown that there were motor fibres in the superior laryngeal nerve and therefore watched two of the cases on which he had sectioned these nerves to see if there were any changes in the movements of the larynx, but the destruction in both of these cases was so great that I was not able to see any difference. However, we have known for a long time that the superior laryngeal nerve is largely a sensory nerve and the pain and discomfort which our patients with extensive lesions of the larynx suffer is intense. Anything which will relieve the painful deglutition which these patients encounter is a justifiable procedure.

I have tried alcohol injection of the superior laryngeal nerve by every technic which I have been able to get hold of, but my results have been uniformly unsuccessful, which is quite in contrast with the results which Dr. Nordland has obtained by sectioning the nerve. The operation is a simple one. The incision is small and heals quickly. It is our practice to remove the skin clips 36 to 48 hours after operation and bridge the incision with sterile adhesive. All of these operations were on advanced, moribund cases of tuberculosis, nevertheless the wounds healed by primary intention.

Dr. A. Schwyzer, St. Paul: This operation is exceedingly well conceived, and it surely is a great boon for our cases. I am only sorry that I did not think of this myself years ago. If one has seen how much these patients suffer and how they are afraid to eat, then to have this relief and the improvement in nutrition which would follow, one cannot help feeling that this is the best thing for such cases. I have at one time used alcohol injection, but the result was transitory. In one case I removed the larynx. You have to be sure that you haven't much involvement in the lung. In the case in which I removed the larynx, it was too much for the patient, for he gradually went down anyway afterwards. As to the technic the doctor uses in his cases, I wondered, when I saw how he proceeds, whether one could not make a median incision between the hyoid bone and thyroid cartilage; one would simply have to go through the sternohyoid muscle and then, by going along the thyrohyoid ligament on both sides, you could get the nerve with great ease as it is the only strand entering this ligament.

Dr. E. K. Geer, St. Paul: I think this procedure has a very definite place in the treatment of ulcerative laryngeal tuberculosis, although a small one. I have used it once (Dr. Colvin doing the operation) on one side on a patient in whom I had been successful with alcohol injection on the other side. Of course, we should not use resection of the superior laryngeal nerve at first because in the majority of cases we can get enough relief by vocal rest, light treatment and applications of local anesthetics such as anesthesin in mild cases and cocaine in severe ones.

Dr. Nordland, in closing: There is just one thing I neglected to mention. This procedure can be used for other things than tuberculosis. It is particularly valuable in relieving the pain from other inflammatory processes, and in carcinoma which invades the larynx.

Dr. Arnold Schwyzer reported a case of ligation for aneurysm of the innominate artery upon which he had operated 22 years ago, and just recently learned that the patient is still living and well.

The meeting adjourned.

R. T. LaVake, M.D.
Secretary.

PROCEEDINGS OF THE MINNEAPOLIS SURGICAL SOCIETY

Meeting of October 1, 1931

The regular monthly meeting of the Minneapolis Surgical Society was held in the Lounge on the 20th floor of the Medical Arts Building on Thursday evening, October 1, 1931.

The meeting was called to order at 8 p. m. by the President, Dr. J. Frank Corbett. There were 26 members and 7 visitors present.

Minutes of the May meeting were read by the Secretary and approved as read.

After a short business meeting, the following scientific program was presented.

Dr. William A. Hansen gave a talk, illustrated with slides, on "The Anatomy of the Breast with Special Reference to the Lymphatics."

Dr. O. J. Campbell read his Inaugural Thesis entitled "End Results of Eighty Carcinomas of the Breast Treated by Radical Operation, with or without X-ray." (To be published in full in a later number.)

ABSTRACT

The paper consists of an analysis of the nature of the material and the end-results obtained in all carcinomas of the breast treated at the University Hospital between the years 1916 and 1928, by radical operation with and without postoperative X-ray therapy.

Out of eighty such cases, there were two males, an incidence of 2.5 per cent as compared to 1 per cent reported by Judd and 1.2 per cent by Pack and Pfahler.

The age incidence is given by table and the maximum found to be in the fifth decade, corresponding to the findings of others. None was under thirty-five or over seventy-five. The incidence of cancer in the young is discussed briefly.

There was an incidence of 7.7 per cent single, 28.2 per cent widowed, and 64.1 per cent married women. In seven there was an indefinite history, and in two a definite history of trauma. Previous breast lesions include four cases of chronic mastitis, two of breast abscess and one each of galactocele, "caking," and benign tumor.

The initial symptom was, in 57.5 per cent, the discovery of a lump, and in 25 per cent, pain. Other symptoms are listed in order of frequency.

A definite preponderance of cancers was noted in the left breast. A table is given for comparison with other reports. The percentage of lesions occurring in the various portions of the breast is given and compared to the findings of others.

The element of delay is discussed in some detail. The mean alleged duration of symptoms for all cases was 19.3 months. When cases of over three years' duration were eliminated, the average dropped to 9.9 months. The average delay occurring between the first consultation with a physician and the beginning of treatment was 4.8 months. In the eleven cases in which poor advice was given the average delay was 12.6 months.

An operative mortality of 3.75 per cent was analyzed and compared to other reports. Of the seventy-seven cases surviving operation, seven have been listed. Follow-up information on seventy cases was available. Because of the method used in tracing patients it was thought safe to consider the lost cases as showing at least as favorable results as the traced cases. The results are therefore analyzed in detail on the basis of the traced cases only, but the totals are also given in relation to the whole material traced or untraced.

Cases were grouped as follows:

Group I. Local tumor without skin or fascial attachments; no glandular involvement on pathological examination.

Group II. Local tumor without skin or fascial attachments; glands involved.

Group III. Skin and fascial attachments; glands involved.

Group IV. Supraclavicular or remote metastases.

There were 23 per cent in the first group, 37 per cent in the second, 33 per cent in the third, and 7 per cent in the fourth.

The results are tabulated as three-year, five-year and ten-year survivals for each group.

Based on available cases only, there were 48.6 per cent three-year, 38.8 per cent five-year, and 24 per cent ten-year survivals.

Based upon total material there were 44.2 per cent three-year, 34.5 per cent five-year, and 22.2 per cent ten-year survivals.

The relationships between delay and results, and between location in the breast and results, are shown by table.

Fifty-nine of the seventy cases were graded according to Broders' classification. A comparison between grade and end-results is shown.

Comparison of results between the present series and other reported series are rendered in tabular form.

Dr. W. A. O'Brien, Pathologist at the University Hospitals, had been invited to give a paper on "The Pathology of Carcinoma of the Breast."

Dr. K. W. Stenstrom, of the department of Radiology at the University Hospitals, had been invited to give a paper on "Radiation Therapy in Carcinoma of the Breast."

DISCUSSION (on four papers)

Dr. A. T. Mann stated he had been greatly interested in some of these questions in regard to cancer of the breast. One point is the pre-operative use of X-ray, and he recalled a patient sent him from New York who had been operated on by one of the best men in New York City, whose statement was that he thought they were getting better results if they did not use pre-operative X-ray. In studying the question a little, Dr. Mann thought possibly the idea is this. As he understood it, X-ray and radium have effects which vary according to the depth of penetration; that is, if one put an X-ray dose onto a tumor and took it away too soon its first effect would be to stimulate that tumor. Then if it was applied more, the effects would be deeper. The effect at the tumor itself would be a destructive dose, but deeper in the tissues it would be an irritative dose. If secondaries are present it is possible that they may be receiving an irritative dose and be stimulated rather than killed; whereas, if there are no secondaries then pre-operative treatment with X-ray might be of value. Dr. Mann said he did not know whether that is really the case, but it seemed that there are several series of statistics which show that the results where the secondary nodes were present are better when the pre-operative treatments are not given.

Dr. Mann called attention to another interesting point and that was the suggestion by Bower and Clark of Philadelphia of taking an impression of the breast, similar to taking finger prints, pre-operatively, of course. Dr. Mann felt that if we could get any information before operating, that the growth is or is not malignant, we have gone a long ways. These men suggested making a print of the breast, which they did in a large series of cases, and in studying them they were surprised to find things on the print which they had not seen with the eye. Most of the skin is different when the tumor is older and they felt that there might be and was something of help in this procedure. Their observation was that in the cases in which there was carcinoma they very often detected that the ridges and sulci, the pores, and the arrangement of the skin were changed, but that where the case was benign those changes were absent. Dr. Mann stated that he merely gave this for what it is worth. He did not know much about it, but it would be good for teaching purposes, and one could file these prints away and have them on record.

Dr. Mann said he was rather disappointed that the clinical index of malignancy did not seem to work out so very well, for on the face of it it is very attractive. Dr. Lee makes the factors which he knows the weighing factors and gives them the following values: Age: 2; lactation, 3; rate of growth, 4; extent of growth, 5; and then modifies that by certain multiples:

The age, if over 55, he put down as 1, *i.e.,* 1 × 2 = 2.
If between 40 and 55 he put it down as 2, *i.e.,* 2 × 2 = 4.
If under 39 or 40 he put it down as 5, *i.e.,* 5 × 2 = 10.
Lactation, if not present, would be 0.
Lactation, if present, he put down as 3, *i.e.,* 3 × 3 = 9.
The rate of growth, if slow, moderate, or rapid, he would put down at 1, 2 and 4, *i.e.,* 4 × 1, 4 × 2, or 4 × 4.
The extent, if below 3 cm. (1 to 0.2 inches) would be first; if over that it would be the second, and if nodes are present, the third. The modifying factors would be 1, 2 and 4.

And he could get right down in figures a very good scale, making his first ones of slight malignancies up to 25 points. The lowest possible points equal 11, and the highest 55. He took up to 25 for his A series, and from 26 to 39 his B series, and from that on up for his C series and tested these out with studies on his old cases. The article Dr. Mann mentioned was the result of a study of 100 cases. His A series had about sixty-eight or sixty-nine patients living at the end of five years, the B series thirty-four, and the C series only one patient.

Dr. H. B. Sweetser stated that first of all he wished to congratulate the program committee and the essayists for a most interesting meeting.

As regards diagnosis of cancer of the breast, he felt sure that one, after having seen and operated on a number of cases, can make a correct diagnosis in almost every case clinically by palpation, and after operation by gross section without microscopic verification, although this, of course, should be done.

Concerning grading as to the degree of malignancy, he was sure that this information should not influence one as to the character or extent of the operation. If the case is cancer, irrespective of type, it should have as extensive and radical an operation as possible; if extension has not gone beyond the reach of surgery, either permanent cure or a great prolongation of life will result. Because some surgeons try for a good cosmetic result, they are liable to remove too little skin and fascia and so have recurrences which might be avoided. When operating, one should forget entirely cosmetics, and if unable to approximate the skin edges, even after extensive undermining, should allow healing by granulation and subsequent grafting. From the standpoint of scientific surgery grading of every cancer is very essential, but from the standpoint of results in the prolongation of life, the type of operation is most important.

Dr. A. A. Zierold stated that both Dr. Campbell and Dr. O'Brien mentioned a point which they had in common and which Dr. Sweetser also mentioned in his discussion, namely, the grading of these cancers. Apparently from the first work done, particularly on cancer of the lip, this proved to be a rather accurate method. From Dr. Campbell's analysis, which has been a very careful analysis even though the series is short, and from what Dr. O'Brien has shown, Dr. Zierold felt that the question might be raised as to whether they were not merely reclassifying cancer on its morphology rather than on its behavior.

In employing the phrase "grade of malignancy" the implication is that the clinical behavior of the tumor is identified according to variations in cell structure. If the method be sound, it would appear reasonable that the behavior of a tumor of a certain grade should be uniform irrespective of the type of treatment employed.

Thus, if Grade IV, which by classification is very active, is radio-sensitive and disappears under this form of therapy but is resistant to surgery, the system of grading fails as a basis of prognosis and again becomes another system of classification.

Dr. Campbell, in response to Dr. Mann's expression of disappointment over the prognostic value of Lee's clinical index, stated that he did not wish to create the impression that the clinical index was not accurate. He felt that, unless the patient was lactating or was very young, the prognosis was equally well reflected in the presence or absence of axillary metastases. Group I cases corresponded to Lee's least malignant group while Groups II, III, and IV corresponded to Lee's group of average malignancy. He said it is almost impossible to get into the most malignant group unless metastases have occurred and unless the patient is either very young or lactating. None of the cases in Dr. Campbell's series fell in this most malignant group.

Dr. Campbell stated that while in the hands of certain individuals the grade of malignancy of breast cancers may closely correspond with the ultimate results, in his series the grade of malignancy as determined by Dr. Randall attempting to use Broders' methods and criteria did not in the least agree with the clinical outcome and was valueless as an index to prognosis.

Dr. R. C. Webb asked how many different surgeons operated on these patients.

Dr. Campbell stated that there had been several but that the operation was standard and varied only as to the type of incision used.

Dr. J. F. Corbett asked what a "radical operation" is and

Dr. Campbell replied that such an operation consisted in the removal of fat and lymph glands of the axilla, pectoralis major and minor muscles, breast, a generous portion of fascia and the upper part of the anterior rectus sheath. No attempt is made to remove supraclavicular nodes. The operation starts in the axilla and finishes at the rectus sheath, all tissues being removed in one block.

Dr. Campbell added that, while he did not mention the point in his paper, it might be well to recall a teaching of Dr. Bevan that the cancer should occupy the center of the block of tissue removed. A great many surgeons will remove the breast without regard to the position of the tumor. If there is anything to the theory that cancer extends by lymphatic permeation, the surgeon is likely to cut through involved lymphatics unless he uses the cancer as the center of the block. The closer a cancer is to the periphery of the breast the greater will be the amount of skin which must be removed.

Dr. K. W. Stenstrom stated that the question of stimulation from radiation is an old one and has been threshed out a number of times at various meetings. A number of years ago it was assumed to stimulate the growth and experiments were carried out on a small scale and these seemed to agree with that assumption. Then those experiments were continued on a larger scale and no stimulation was obtained. Dr. Stenstrom said, so far as he knew, there has been no actual stimulation of tumor growth in patients. Of course one cannot deny the possibility of it, but it seemed to him that if it were present we should see poorer results than we do from the use of radiation. When they have a far advanced case they always give some of the metastasis a small dose and still those patients live a little longer, according to statistics, than do those untreated.

Dr. Stenstrom said he wished to call attention to another theory which was just the opposite, and that is that if one treated one part of the tumor a defense was set up against the rest of the tumor. Some experiments were done by Caspari, Opitz and others in which the whole mouse was irradiated except the tumor area and they noticed in some of the experiments that the tumor decreased, but Dr. Stenstrom felt there was very little to that theory with respect to the tumor in humans. He felt that now the majority of radiologists feel that there is no direct stimulation to the growth, and the so-called stimulation obtained in certain diseases might be some kind of indirect stimulation.

The President closed the meeting by extending the thanks of the members of the Society to the visiting essayists who contributed to the program.

The meeting adjourned.

H. O. McPheeters, M.D., Secretary.

MINNESOTA PHYSICIANS—ATTENTION

This is to request respectfully that patients be not sent to the University Hospital unless the hospital has been called by you, and the hospital has agreed to accept the patient. Lately, some of the doctors have been sending patients without such notice. This, of course, is unfair to patients. The hospital is crowded, and is unable to accept patients unless we know they are coming.

In fairness to the patient, we request that you comply with our wishes in this matter.

Paul H. Fesler, *Superintendent.*

PERNOCTON NOT ACCEPTABLE FOR N.N.R.

Pernocton, stated to be a 10 per cent solution of the sodium salt of the secondary butyl-beta-bromallyl barbituric acid, was submitted to the Council on Pharmacy and Chemistry by Riedel-de Haen, Inc. The product is proposed for intravenous injection for production of "Pernocton sleep." Since the name is therapeutically suggestive, the firm proposed to replace it with "Pernoston" and requested consideration of the product under the latter name; however, advertising as late as May, 1931, still bears the name Pernocton. The Council on Pharmacy and Chemistry declared the name Pernocton therapeutically suggestive and held the product, whether marketed as Pernocton or Pernoston, unacceptable for New and Non-official Remedies for lack of critical evidence that routine intravenous injection of potent narcotics is desirable or safe. (Jour. A. M. A., October 3, 1931, p. 1001.)

CONSULTATION BUREAU

Wm. A. O'Brien, M.D., *Director*

Minnesota State Medical Association
11 West Summit Avenue
Saint Paul, Minnesota

This service will be discontinued January 1, 1932, by action of the Council at its last regular meeting, October 30, 1931.

1. *Question.*—I have an old man with osteomyelitis of the clavicle near the shoulder joint. It has persisted for about two years, with a small amount of discharge and an occasional passage of a few spicules of bone. I would like to try the maggot treatment on him and wish to know where I may obtain the eggs.

   Answer.—Maggot eggs may be obtained from Lederle Laboratories (New York) in bottles of 1,000 each. As it takes approximately eight or nine bottles for a course of treatment, the cost is about sixty dollars for the series. The eggs are implanted in the wound, the entire content of one bottle being used for a treatment. It is necessary to renew them at about five day intervals, before the pupa stage is reached. The treatment is harmless and frequently successful. The usual treatment of osteomyelitis of this type is subperiosteal resection of the diseased area. It is usually successful and is recommended. The maggot treatment was described in detail in the July issue of the Journal of Bone and Joint Surgery, this year.

2. *Question.*—What do you consider the best method for immunization against scarlet fever? Give the results and possible period of immunity.

   Answer.—Obtain scarlet fever toxin prophylactic (Dick) from Squibb. Give five doses in all at weekly intervals. The child may then be tested with Dick toxin for skin reactions. Interest seems to be waning in this procedure at the present time as it is impossible to predict in an individual case the end-result. Some children have been immunized apparently with success, while others have contracted the disease in spite of the injections. Apparently favorable results are obtained when large series are studied. By comparing the immunized and non-immunized children some protection seems to have been afforded the former group. In an individual case the parents may be told of these possibilities, and if they still desire the injections they can be given.

3. *Question.*—We have been having trouble with dry sterilization of our rubber gloves. What method do you use?

   Answer.—The gloves should be dried and powdered. Folding the cuff back is optional. They are then wrapped loosely in cloth and the edges held together by paper clips. Caution should be observed in not clipping the gloves to the cloth. They are then placed in an autoclave and subjected to fifteen pounds pressure for fifteen minutes. The pressure and time factor are very important as sixteen pounds pressure seems to have bad effects, etc. If the gloves are boiled, a longer time should be used.

4. *Question.*—I have a child who gets convulsions in her sleep. She is very bright, nine years old, and gets along well in school. The parents are concerned over the possibility of epilepsy as the convulsions have just started recently. How is it possible to distinguish epileptic from other convulsive seizures?

   Answer.—The differential diagnosis of convulsions is often difficult. The fact that your patient has just started to have them recently is suggestive of epilepsy. A careful history of each attack is necessary. Better still would be an opportunity to observe her in one. As a general rule, if patients hurt themselves, *i.e.,* bite their tongue, and lose sphincteric control, the condition is probably epilepsy. Be slow in making a diagnosis until you get all of the facts in the case.

5. *Question.*—At a recent staff meeting, the question of blood chemistry came up for discussion. It was brought out that many of the men write orders for blood urea nitrogen, creatinine, and uric acid on new patients. Some one suggested that blood urea nitrogen was sufficient and the other tests were not necessary unless it was elevated. It has recently come to my attention that many hospitals have substituted nonprotein nitrogen determinations for blood urea tests. Which method do you think is the best?

   Answer.—It is unnecessary on new patients to order blood urea nitrogen, creatinine, and uric acid. A single order for blood urea nitrogen is all that is needed in most cases. Many hospitals are now doing nonprotein nitrogen determinations instead of blood urea nitrogen. The values usually given are 25 to 35 mg. per 100 c.c. of blood. Amounts up to 50 mg. may not be significant in a clinical way. It appears that there is a growing tendency to use nonprotein nitrogen more and more for the determination of nitrogenous retention in renal insufficiency. All the tests indicate the same thing, normal or increased nitrogen values.

6. *Question.*—Young married woman, 18 years of age, gives history of intermittent attacks on right side that seem quite typical of ureteral colic. In some ways they are less severe than those due to stone. They have been present for more than a year and last from a day to a week. Between spells, she feels fairly well. She has never had any symptoms of bladder irritation. The patient has lost thirty-five pounds in weight in two years but now appears to be about normal. She has never been pregnant. Physical examination is negative except for moderate tenderness in the region of the right kidney. She was observed for four days in a hospital and did not show any elevation of pulse or temperature. Urine is cloudy, shows a trace of albumin, and moderate amount of pus. Flat films show no evidence of stone. Skiodan was given and an irregularity and distortion of the right pelvis was seen. Five hours later, no shadows were present. What are the diagnostic possibilities?

   Answer.—An infection of the kidney can give this picture. While these conditions are sometimes called pyelitis, pyelonephritis is usually a better term. There is a remote possibility that the lesion is tuberculous, and perhaps it would be better to rule it out. The usual cause is the colon bacillus. Treatment consists of forced fluids, alkalinization of urine, bed rest, and use of urinary antiseptics. It may be necessary to try ureteral drainage and lavage. The possibility of association with the weight loss must be kept in mind. Sometimes this results in ptosis of the kidney and defective drainage and must be corrected before improvement will take place.

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

The Rockefeller Foundation. Annual Report, 1930. Illus. 380 pages. New York: The Rockefeller Foundation, 1931.

Infections of the Kidney. Meredith F. Campbell, M.D., F.A.C.S., Attending Urologist, Babies Hospital, New York Nursery and Child's Hospital, etc. 343 pages. Illus. Price, $3.00. New York: Harper & Brothers, 1931.

ROENTGEN INTERPRETATION; A MANUAL FOR STUDENTS AND PRACTITIONERS.

George W. Holmes and Howard E. Ruggles. 339 pp. $5.00. Philadelphia, Lea and Febiger, 1931.

The fourth edition of "Roentgen Interpretation" by Holmes and Ruggles continues to be the same useful ready reference book in roentgen diagnosis as its predecessors, brought up to date by the addition of recent advances in roentgenology. This edition now includes such newer procedures as salpingography, encephalography and intravenous urography. The portion devoted to the Graham-Cole method of gallbladder study has been revised to include recent changes. In several instances new roentgen diagnoses have been added. Though in no way radically changed, the fourth edition of this concise book is again abreast of the times in roentgen diagnosis and will continue to be useful to most any one interested in roentgen interpretation.

J. Richards Aurelius, M.D.

THE NURSES' MEDICAL LEXICON. For the Use of Graduate and Student Nurses, of Premedical and Dental Students and of the General Public. Thomas Lathrop Stedman, A.M., M.D. Price $2.00. New York: William Wood and Co., 1931.

This moderately sized volume prepared by the author of "A Practical Medical Dictionary" as the title indicates specially for the use of nurses, recommends itself because of the convenient and not too condensed size of the volume and also because of its price.

WANTED—Salaried appointments for Class A Physicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nation-wide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan Ave., Chicago. Established 1896. Member The Chicago Association of Commerce.

FOR SALE—Office equipment including X-ray. Location in Minnesota town of 1,400 people. Average income of over $5,000 yearly for the past eight years. Unopposed. Specializing. Address D-150, care Minnesota Medicine.

PRACTICAL NURSE—Graduate Clinical Laboratory and X-ray, desires work. Hospital or doctor's office. Good references. Emilie Giske, 3509 45th Ave. South, Minneapolis, Minn.

WANTED—Position in Clinic or Physician's office. Two years' experience laboratory, X-ray technician. Basal metabolism and physiotherapy. $95. Age 26. Address Florence Frey, Hillsboro, Wisconsin.

AN EXCEPTIONALLY GOOD LOCATION for a physician. Call or write C. A. Cavanaugh, druggist, 2901 Washington Ave. North, Minneapolis.

FOR SALE: Victor X-ray fluoroscope in excellent condition. Telephone, Main 4656, 601 Medical Arts Bldg., Minneapolis.

FOR SALE—Serialograph, also Universal Junior X-ray Apparatus and Tube Stand. Address D-153, care Minnesota Medicine.

MINNESOTA GRADUATE PHARMACIST wants position in dispensary or laboratory. Hospital dispensing and analyzing preferred. Ready now. Best references. Address D-154, care Minnesota Medicine.

COMPETENT LABORATORY AND X-RAY TECHNICIAN wishes work in doctor's office, clinic or hospital. Will accept small salary to prove worth. Violet H. White, Galena, Illinois.

Dr. J. C. Michael

A new, fireproof building, airy and cheerful, facing the south. Every room an outside room with a pleasant outlook. Thoroughly equipped as to operating rooms, x-ray and pathological laboratories, medical, surgical and obstetrical departments. An efficient staff of doctors. An adequate nursing service. An accredited school of nursing.
The Hospital's Aim: An adequate service in a cheerful atmosphere at reasonable cost.

MISS LYDIA A. MILLER, R. N., Supt. Asbury Hospital, 916 East 15th Street, Minneapolis, Minn.
